Kidney and Abdominal Protector

M.D., F.R.C.S. Eng., writes:—

"This Protector is designed for the use of men and women. Covering the abdominal and pelvic organs, it will prove useful to those men who are exposed by their occupations to the vagaries of the weather, especially when the occupation involves sitting or standing for long periods. To adult women of all ages and to adolescent girls it will be a safeguard against the special ailments which are so liable to be brought on by exposure to cold." *From Principal Chemists.*

HOOKER'S

is a New & Improved MALTED MILK

IN SOLUBLE POWDER FORM.

Manufactured from selected materials by a recently perfected process, which eliminates all deleterious substances and presents a most nourishing and palatable food product, possessing distinct advantages in feeding infants, growing children, and for general use in the home.

IS AN ENTIRELY BRITISH PRODUCT

Sold by Chemists & Stores in Sterilized Bottles at 1/6½, 2/6½, & 6/8 each

Members of the Profession are invited to send for Sample which will be sent Free by post on application to—

THEW, HOOKER & GILBEY, LTD., BUCKINGHAM.

Emol-Keleet

THE NATURAL SEDATIVE EMOLLIENT DUSTING POWDER.

Children's Rashes and Sensitive Skin

IN seeking a means of affording immediate relief from the irritation of erythema; of the nettle rash; of the crimson rash that accompanies measles, or of the scarlet rash in scarlatina, the physician may rely with absolute confidence on Emol-Keleet. This excellent dusting powder is purely inorganic in composition, impalpable in texture, mildly astringent, and pleasantly sedative.

Its beneficial influence in all cases of disturbed or irritated affections of the skin, and especially in inflammatory or purulent cases, is most marked.

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, Ltd., 86, Clerkenwell Rd., London, E.C.

PRINTED and PUBLISHED by the PROPRIETORS, WAKLEY AND SON (1912), LTD., at No. 423, Strand, and Nos. 1 and 2, Bedford-street, adjoining, in the County of London.—Saturday, Dec. 1st, 1917.

MACMILLAN'S LATEST LIST.

LORD LISTER. By Sir RICKMAN JOHN GODLEE, Bart., K.C.V.O., F.R.C.S. With Portraits and other Illustrations. 8vo. 18s. net.

The BRITISH MEDICAL JOURNAL:—"Successful biography depends on two essentials—a fit subject and a proper manner or style in the representation—that Lord Lister is one of the great figures in the history of the healing art there can be no question, and that Sir Rickman Godlee has provided a memoir that will live as one of the great biographies every competent critic must cordially agree."

THE NEW SYSTEM OF GYNÆCOLOGY.

Edited by THOMAS WATTS EDEN, M.D., F.R.C.S.E., F.R.C.P.; and CUTHBERT LOCKYER, M.D., B.S., F.R.C.S., F.R.C.P.

In Three Volumes. With numerous Illustrations in Colour and Black-and-White. Crown 4to. £6 6s. net.

DUBLIN JOURNAL OF MEDICAL SCIENCE:—"No gynæcologist should be without it. ..... Printed clearly on good paper, strongly bound, profusely illustrated, the publication of the 'New System of Gynæcology' is a landmark in the history of the subject."

VOLUME IV. JUST PUBLISHED.

Human Physiology. By Prof. LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome.

Translated by FRANCES A. WELBY. With a Preface by J. N. LANGLEY, F.R.S., Professor of Physiology in the University of Cambridge. Illustrated. In 5 Vols. 8vo. 21s. net each.

Vol. I.—CIRCULATION AND RESPIRATION.
Vol. II.—INTERNAL SECRETION—DIGESTION—EXCRETION—THE SKIN.
Vol. III.—MUSCULAR AND NERVOUS SYSTEMS. Edited by GORDON M. HOLMES, M.D.

The Third Edition.

Moynihan's Abdominal Operations

Revised and Enlarged.

Abdominal Operations. By Sir BERKELEY MOYNIHAN, M.S. (Lond.), F.R.C.S. Two octavos, totalling nearly 1000 pages, with 385 illustrations.

Per set: Cloth, £2 6s. net.

. . . . PRESS OPINIONS . . . .

From the British Medical Journal.

"We cannot praise this work more highly than to say that it is well worthy the reputation of its author, and that it should be the cherished possession of every active-minded surgeon."

From The Lancet.

"It is needless to discuss the whole work in detail, but we may say that in this, as in the other writings of the author, the facts are given in simple language, and he speaks with the assurance of one who knows his subject. The illustrations are numerous and clear, and the printing is all that can be desired."

From the Edinburgh Medical Journal.

"The writer's facile style, the clearness of the type, and the excellence of the illustrations, all go to make the book one which is read with pleasure as well as profit. Each successive edition of such a work must find a place in the operating surgeon's library."

From the Dublin Journal of Medical Science.

"It would be an impertinence to attempt to criticise such a work from such a distinguished surgeon and writer as we all know the author to be. It is sufficient to state that the work has been thoroughly revised and has been placed within reach of all in the author's best manner. The illustrations and letterpress are also all that could be desired."

From the British Journal of Surgery.

"The book, which is got up in Messrs. Saunders' usual perfect style, and illustrated by many excellent drawings by Miss Ethel Wright, will remain a monumental and authoritative work on the surgery of the alimentary canal and its glands."

History of Medicine

Just Issued
New (2nd) Edition

"Dr. Garrison's book is the most readable and in some respects the most valuable, of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull; his book, though heavy to hold, is light to read. We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."—BRITISH MEDICAL JOURNAL.

History of Medicine. With Medical Chronology, Bibliographic Data, and Test Questions. By FIELDING H. GARRISON, M.D., Principal Assistant Librarian, Surgeon-General's Office, Washington, D.C. Cloth, 28s. net.

The Modern Hospital

Efficiency in Hospital Administration

"We should recommend all those who have to deal with the administration of our hospitals to consult this book before they decide on any plan of reconstruction or equipment of the hospital under their charge."
—DUBLIN JOURNAL OF MEDICAL SCIENCE.

The Modern Hospital; Its Inspiration, Its Architecture, Its Equipment, Its Operation. By JOHN A. HORNSBY, M.D., Secretary, Hospital Section, American Medical Association; and RICHARD E. SCHMIDT, Architect. Octavo of 644 pages, with 207 original illustrations. Cloth, 30s. net.

Scudder's Treatment of Fractures

Eighth Edition

"Is one of the best of modern works on the subject, and with its full and lucid teaching, supplemented by an abundance of excellent illustrations, will be found a useful guide in the management of this class of injuries."—BRITISH MEDICAL JOURNAL.

By CHARLES L. SCUDDER, M.D., Surgeon to the Massachusetts General Hospital, Boston. Octavo of 735 pages, with 1057 original illustrations. Cloth, 25s. net.

W. B. SAUNDERS COMPANY, 9, Henrietta Street, London, W.C. 2.

The more money you invest in NATIONAL WAR BONDS to-day, the more money you will have to spend on good books to-morrow.

THE
MEDICAL ANNUAL, 1917
BY TWENTY-SEVEN DISTINGUISHED CONTRIBUTORS.

This year's Volume has a unique value, for while the civil side of the Practitioner's work has received every attention as before, it also provides a careful review of the latest achievements in War Surgery and Medicine which cannot be obtained from any other single source. This will be of value to every Practitioner in dealing with such cases, with which he will inevitably be confronted now and in the years to come.

Thus the new "Annual" continues to be a digest of the best modern teaching, culled by experts from the medical literature of the world.

Use a Douglas Motorcycle

NIGHT calls are urgent. Delay in responding may be fatal to the patient. Every doctor should be in a position to answer night calls without the loss of a single moment.

That is one reason why every doctor should ride the clean, speedy, handy little DOUGLAS Motorcycle which gives you four times car mileage to the gallon of spirit and takes you to your patient's door as spick and span as when you started.

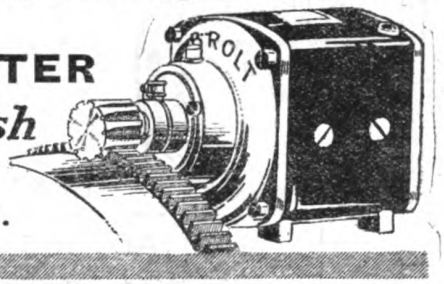
The Ministry of Munitions will grant you a permit entitling you to immediate delivery.

May we send YOU full particulars to-day?

DOUGLAS BROS., Kingswood, BRISTOL.

Douglas

The BROLT was the first British Starter to automatically engage the Engine Fly Wheel. It has long since passed the experimental stage. Thousands are using it to day after lengthy experience. You can therefore adopt it with full confidence—it *cannot* fail—a touch of the switch and the engine starts instantly.



Write for Catalogue.

The **Brolt** Electric
ENGINE STARTER
The First British Gear driven Starter.

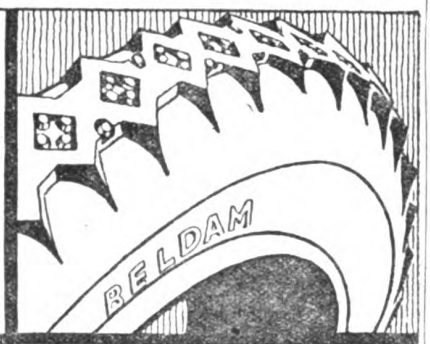
The Right Idea at the Start.

Both Manufacturer and Motorist were quick to realise the value of the "BROLT" positive and silent gear drive, because they saw in it a safer, surer self-starter. That this original idea is the most practical is exemplified in its more general adoption to-day.

THE SINGER "10"

AN IDEAL DOCTOR'S CAR

A FEW OF THE FAMOUS **SINGER "10's"** ARE NOW AVAILABLE FOR EARLY DELIVERY TO THOSE ABLE TO OBTAIN PERMITS FROM THE MINISTRY OF MUNITIONS.



PRECEDENCE IS USUALLY GIVEN TO DOCTORS.

If would-be Purchasers so desire, we will supply them with the necessary form of application.

Write to-day for full particulars—

The Pre-War Quality

of Wolsey has not been tampered with—however long the War may last, the quality of Wolsey will not vary. Wolsey is always made from pure, new, clean wool—British labour makes it into reliable, unshrinkable underwear. The manufacturers of Wolsey are busily engaged in making millions of garments for the troops. As our soldiers' and sailors' needs increase and Government demands grow more insistent Wolsey becomes more difficult to get. But Wolsey is worth waiting for. Wool costs more—the price of Wolsey—being pure wool—is raised in consequence.

Wolsey

Pure Wool Underwear

Wolsey has been medically recommended for over fifty years, and is no less worthy of the profession's strong support to-day.

As in future civilian requirements of Wolsey may not be so readily obtainable, it is advisable to order in advance. Wolsey is worth waiting for.

Wolsey is made for men, women, and children. Any garment that shrinks is replaced free of cost.

13

Prescribed by the Medical Profession for 35 years.

The BRITISH MEDICAL JOURNAL says:
"Time and use have justified the claims put forward for these preparations."

BENGER'S FOOD—

Describing how and why it is different to all others.

BENGER'S FOOD is a specially prepared wheaten food with which is combined two active natural digestive principles (enzymes), viz., Amylopsin and Trypsin. It is devised to be used in conjunction with fresh cow's milk, which it enriches and partially digests (more or less as desired) before consumption.

ITS ADVANTAGES. It provides a freshly prepared and delicious food cream, entirely free from irritant particles, of delicate biscuit flavour, and incapable of forming heavy curd when in contact with the acid contents of the stomach. While it is a most easily assimilated food, it is most nourishing.

ITS USES. It is relied upon in stomach and intestinal complaints and infectious diseases, and, as a supplementary food, it is especially valuable in minor ailments and mal-nutrition. For nursing mothers, it is very valuable, and is most successful as a transfer food at weaning.

BENGER'S Food

for INFANTS, INVALIDS, AND THE AGED.

is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

GOLD MEDAL, LONDON, 1908
Grand Prix, Nancy and Quito, 1909
Hors Concours, San Francisco Exhibition, 1915

COMMUNICATIONS:
Academy of Medicine, Paris, 10th Nov., 1908.
Academy of Sciences, Paris, 14th Dec., 1908.

URIC ACID is never found free in the organism. It always exists in a state of combination with Soda, Ammonia, &c.; it forms biurates or quadriurates, which are complex and not easily soluble.

URODONAL by reason of its special composition, is able to effect the double chemical decompositions which liberate the Uric Acid from the combinations where it is fixed, and cause it to be easily eliminated in the urine.

URODONAL is a most powerful solvent of **URIC ACID,** because it can destroy its organic combinations.

URODONAL.—Price 5/- and 12/- per bottle.
Prepared exclusively at CHATELAIN'S Laboratories, 2 & 2 bis, rue de Valenciennes, Paris.
Can be obtained from all Chemists and Stores, or direct from the Sole British and Colonial Agents—

Trial Supplies and Full Descriptive Literature sent on application to **HEPPELLS** *at the above Address.*

A conclusion based on trials in Hospital and in Private Practice of

'Wander' Malt Extract with Paraffin.

(50% Pure Liquid Paraffin.)

During the last year a large number of trials of this interesting product have been made. Many practitioners have kindly furnished us with reports as to the results. One definite conclusion arrived at by a study of these reports is that the product possesses distinct advantages in the treatment of **Constipation in Children and Infants.**

The almost general unanimity of opinion as to its success in this field of use is ascribed to the following features:

1. Extreme palatability—young patients take it with avidity.
2. Though containing 50% by weight of Pure Liquid Paraffin, it is not oily in nature, being presented in a dry, crystalline powder form.
3. Ease and variety of methods of administration. It mixes instantly with water or milk and does not separate—can also be given on bread and butter or dry from a spoon.
4. The oil being in an extremely fine state of globular division mixes rapidly and completely with the intestinal contents, thus not only lubricating the fæcal mass, but preventing the formation of scybala, and ensuring soft, homogeneous stools.
5. The nutrient, digestive and slightly laxative qualities of the "Wander" Malt Extract being retained unimpaired add to the value of the product and make it an ideal medium in a large number of cases where dyspeptic and badly-nourished conditions are also present.
6. That in the case of Infants' Constipation it can be administered in half to one teaspoonful doses, mixed with a little water, or milk, after feeding, or in the case of the artificially fed, mixed with the contents of the bottle. Its addition to cow's milk also prevents the formation of indigestible curds, and supplies the deficiency of carbohydrate. For these purposes the preparation is stated to be ideal.

The product has been used with advantage in many conditions where Paraffin is indicated, viz.: in **Hæmorrhoids, Stasis, After Intestinal Operations, Typhoid Convalescence, Mucous Colitis, Thread-Worm Infection and Intestinal Toxæmia.**

℞ "*Wander*" *Ext. Malti c. Paraffin.*

Members of the medical profession are invited to write for liberal clinical trial packages.

COLLOSOL IODINE

CROOKES'

COLLOSOLS are Drugs in the COLLOID STATE.

COLLOSOLS are isotonic and isomorphic with the elements of the body.

COLLOSOL IODINE is prepared in aqueous solution, as an Oil, an Ointment, and as a Pasta.

The following extract from an article by one of the foremost dermatologists, in the *British Medical Journal* of May 12th, 1917, testifies to the efficacy of **COLLOSOL IODINE OIL** in the treatment of

CHILBLAINS.

"In a severe case of chilblains in the first stage, that of a woman of 37, whose fingers were so swollen that they looked like sausages, under the application of Collosol Iodine Oil rubbed in four or five times a day every trace of the condition disappeared in four days."

COLLOSOL SULPHUR

Prepared for Internal administration, as an Ointment, and for use in Sulphur baths. Indicated in **RHEUMATIC** conditions and **SKIN** affections.

The above-quoted medical authority, in the same issue of the *British Medical Journal*, stated :—

"Among the affections in which Collosol Sulphur is beneficial are various forms of acne, including acne rosacea and seborrhœa. ..... In the case of an officer from the front, who was crippled with fibrositis and had severe eczema, a daily Collosol Sulphur bath relieved him of all his symptoms in a week."

COLLOSOLS are prepared for the Proprietors, Crookes' Collosols Ltd., at

THE CROOKES' LABORATORIES,

50, Elgin Crescent, LONDON, W. 11.

SQUIRE'S TERPEROIN, CORISOL & CINNAMAL PREPS.

TERPEROIN (REGD.) ELIXIR

(SQUIRE).

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

SQUIRE'S TERPEROIN ELIXIR affords immediate and welcome relief in the troublesome cough of PULMONARY PHTHISIS. It is prescribed with striking success in ASTHMA, Emphysema, Acute and Chronic BRONCHITIS, Laryngeal Catarrh, and in PERTUSSIS.

PAST. TERPEROIN COMP.

(SQUIRE).

DOSE—One or two occasionally.

COMPOUND TERPEROIN PASTILLES present the therapeutic constituents of the ELIXIR in an exceptionally convenient form. They immediately and effectually relieve a distressing cough.

"Both ELIXIR TERPEROIN and PAST. TERPEROIN CO. (SQUIRE) have been found extremely useful in the diseases incidental to WAR."—THE PRACTITIONER.

CORISOL (REGD.)

CORISOL contains the specific Hormone of the Suprarenal Gland in a soft Petroleum base. It affords immediate and effective relief in CORYZA, and is prescribed with great success in EUSTACHIAN and POST-NASAL CATARRH.

CINNAMAL (REGD.)

DOSE—10 to 30 minims = 0·6 to 1·8 c.c.

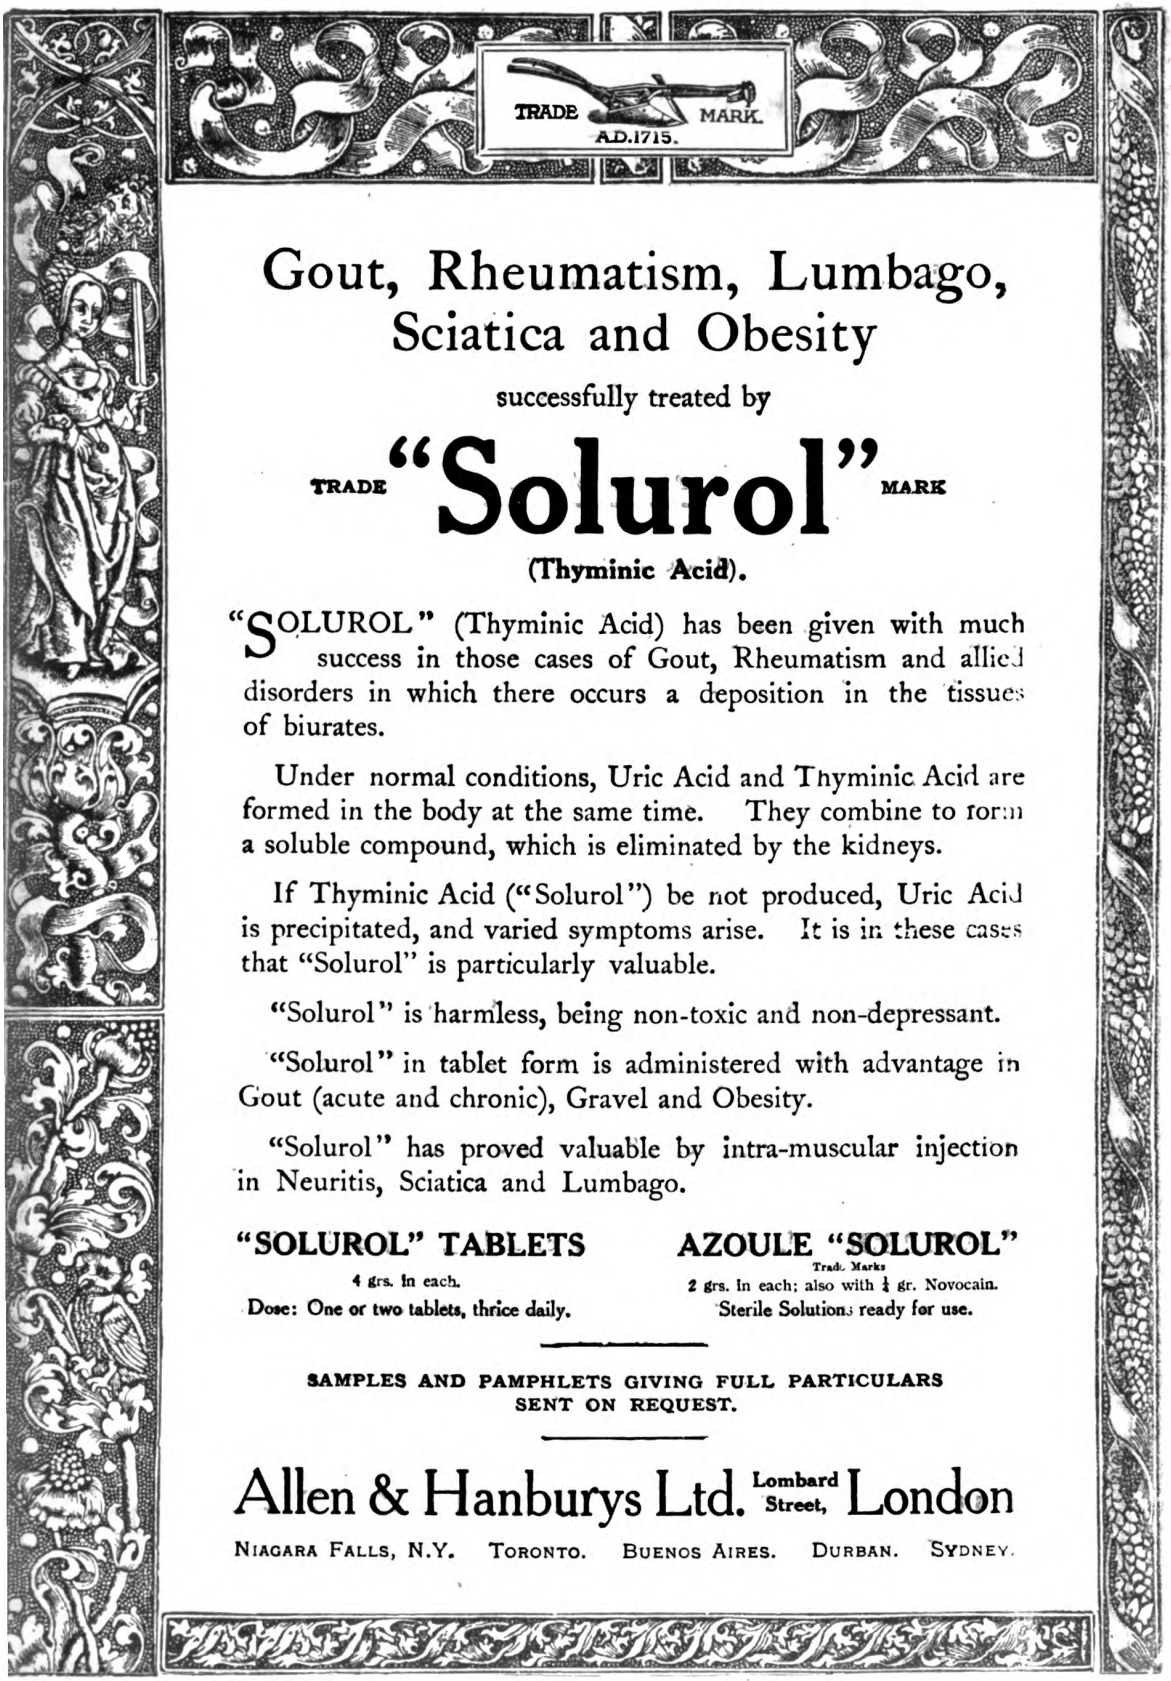
SQUIRE'S CINNAMAL is an antiseptic fluid which affords a valuable precaution against INFLUENZA.

CINNAMAL WITH QUININE

DOSE—10 to 30 minims = 0·6 to 1·8 c.c.

SQUIRE'S CINNAMAL WITH QUININE is particularly valuable as a precaution against INFLUENZA, and is also useful in CORYZA and CATARRH.

CINNAMINT (REGD.) TABLETS



DOSE—One or two tablets as required.

CINNAMINT TABS. are a portable and convenient form of CINNAMAL, and are particularly serviceable as a precaution against INFLUENZA.

Descriptive leaflets gratis on application.

Gout, Rheumatism, Lumbago, Sciatica and Obesity

successfully treated by

TRADE "Solurol" MARK

(Thyminic Acid).

"SOLUROL" (Thyminic Acid) has been given with much success in those cases of Gout, Rheumatism and allied disorders in which there occurs a deposition in the tissues of biurates.

Under normal conditions, Uric Acid and Thyminic Acid are formed in the body at the same time. They combine to form a soluble compound, which is eliminated by the kidneys.

If Thyminic Acid ("Solurol") be not produced, Uric Acid is precipitated, and varied symptoms arise. It is in these cases that "Solurol" is particularly valuable.

"Solurol" is harmless, being non-toxic and non-depressant.

"Solurol" in tablet form is administered with advantage in Gout (acute and chronic), Gravel and Obesity.

"Solurol" has proved valuable by intra-muscular injection in Neuritis, Sciatica and Lumbago.

"SOLUROL" TABLETS

4 grs. in each.

Dose: One or two tablets, thrice daily.

AZOULE "SOLUROL"

Trade Marks

2 grs. in each; also with ¼ gr. Novocain.

Sterile Solutions ready for use.

SAMPLES AND PAMPHLETS GIVING FULL PARTICULARS SENT ON REQUEST.

For Invalids, Dyspeptics and the Aged.

'Allenburys' The DIET

Invaluable in Sickness and Convalescence.

TITLE IMPORTANT

The "Allenburys" DIET is a complete food chiefly intended for Adults, and is *quite distinct* from the "Allenburys" Foods for Infants. It is quickly prepared, exceptionally palatable, easily digested and wholly nourishing.

COMPOSITION & PREPARATION

The "Allenburys" DIET is made from pure, rich, full-cream milk and whole wheat, both ingredients being partially pancreatised during the process of manufacture. It needs boiling water only to prepare it for use.

ANALYSIS

Fat	15·4
Proteid	15·2
Soluble Carbohydrate ...	47·2
Starch	15·7
Mineral Matter	4·3
Moisture	2·2

Caloric Value of the "Allenburys" DIET when prepared ready for use:

Fat	23·8
Proteid	10·4
Carbohydrate	42·9

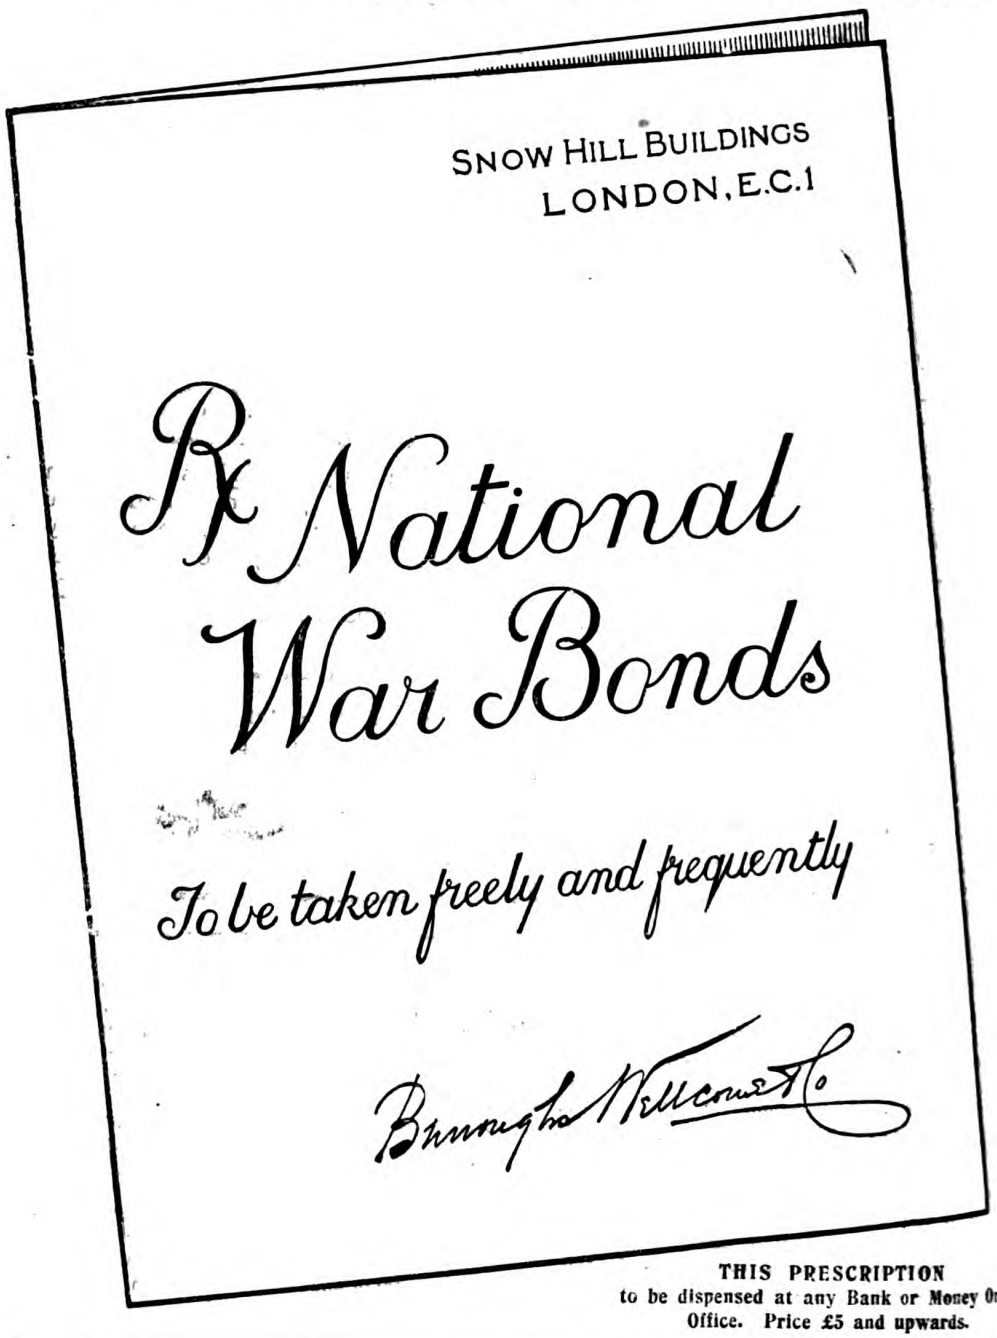
INDICATIONS FOR USE

In all Gastric conditions where it is found that curd is not digested, Gastritis, Gastro-Enteritis, Gastric Catarrh, Gastric Ulcer, Gastric Influenza, Obstinate Vomiting. In all Acute Disorders. Before and after Surgical Operations. In Convalescence, Gouty Dyspepsia, Insomnia, (taken last thing at night it promotes refreshing sleep and digestive rest). Neurasthenia. All forms of Tuberculosis. In Senile Disorders of the Digestion. When pure milk is not obtainable, viz., on Board Ship, in Tropical Countries or Distant Lands, or whenever a light nourishment is required. For the Invalid, Dyspeptic, and the Aged it is an essential nutrient.

ADVANTAGES

Most invalids' foods require cow's milk to be used in their preparation; this involves much time and careful mixing to avoid the presence of burnt milk or lumpiness—common characteristics of foods so prepared. The "Allenburys" DIET does not require cow's milk to be added. By the simple addition of boiling water a complete food is produced that is smooth to the palate and pleasant to the taste. The "Allenburys" DIET can be taken for prolonged periods without any distaste arising. These distinct advantages are of immense service in the work of a busy hospital or understaffed sick-room.

MANUFACTURED BY



Allen & Hanburys Ltd., Lombard St., London.

Prices: In sealed tins 2/- and 4/- each.

'Allenburys' The DIET

HG 78

Rich in Diastase.

Maltine

Rich in Phosphates and Proteids.

The BRITISH MEDICAL JOURNAL says:—

"Clinical experience enables us to recommend it ('MALTINE') as a nutritive and digestive agent, in virtue of its albuminoid content and its richness in phosphates and diastase."

THE LANCET says:—

"'MALTINE' exhibits in an eminent degree the starch-dissolving power of diastase; in fact, a teaspoonful is capable of converting instantaneously a surprising amount of stiff starch paste into a thin limpid liquid."

"**MALTINE**" is readily distinguished from other extracts of malt by its agreeable flavour, convenient consistence, and attractive colour. Its **diastasic** strength, richness in reconstructive constituents, and easy assimilability are the **facts** which explain its use by medical men.

INDICATIONS:

(1) As a nutrient in feeble nutrition and wasting disease.

(2) As a starch digestant to aid feeble amylaceous digestion.

(3) In fever and milk diets, to supplement nutrition and to prevent coarse curdling.

(4) In Infant Feeding, to humanize cow's milk.

(5) As a vehicle and emulsifying agent.

(6) As a natural counteractant to constipation in infants and children.

(7) As a galactagogue.

The word "MALTINE" is our Trade Mark. In prescribing, kindly specify "MALTINE COMPANY."

THE MALTINE MANUFACTURING CO., Ltd., 183, Acton Vale, London, W. 3,

Will be pleased to send Specimens Free of Charge to Medical Men.

"DRY PEPTONOIDS" SOLUBLE (Carnrick & Co.)

BEEF, WHEAT, and MILK

PRE-DIGESTED by ENZYMES.

THE LANCET reports, November 27th, 1915:—

"The pre-digestion is evidently complete, inasmuch as 'Dry Peptonoids' dissolve to a practically clear solution even in cold water. The taste is attractive, a malt flavour being more in evidence than anything else. Our analysis gave the following results: Moisture, 5·00 per cent.; mineral matter, 8·2 per cent.; proteins, 38·80 per cent.; and total sugars, 48·00 per cent. The preparation is one of distinct merit, and should serve as a rapid nutrient, especially in cases of digestion enfeebled by illness."

"**LIQUID PEPTONOIDS**" is a palatable solution of the same food principles —Beef, Milk, and Wheat Pre digested—that constitute "DRY PEPTONOIDS."

CARNRICK & CO., Limited, 183, Acton Vale, London, W. 3.

Will be pleased to send Samples Free of Charge to Medical Men.

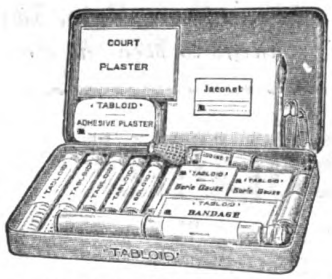
TRADE MARK 'TABLOID' BRAND



Medical Outfits

For Combatant Officers and Men

No. 109 'Tabloid' Medicine Pocket-Case

Specially fitted with emergency medicaments and dressings for use in the trenches, etc. Has proved of real service and is much appreciated at the front. The contents are of exceptional quality and the container is strongly made of metal and black japanned. It fits the pocket.

Price in London, **7/6** (approx.)

No. 109. 'Tabloid' Medicine Pocket-Case
Measurements: 6¼ × 3¼ × ⅞ in.

Outfits obtainable through all Chemists. See also Wellcome's Medical Diary.

No. 131 'Tabloid' Medicine Pocket-Case
(Book-form)

A very serviceable outfit containing 'Tabloid' and 'Soloid' medicaments, 'Tabloid' dressings, and other products for emergency use in the trenches. Light, compact strongly made case. Closes with snap-fasteners.

Price in London, from **13/6**

No. 131. 'Tabloid' Medicine Pocket-Case
Measurements: 6 × 3½ × 1⅜ in.

Physicians are invited to inspect the Firm's Equipments and Products at their

LONDON EXHIBITION ROOM: 54, WIGMORE STREET, W.

Representatives are there to give information and demonstrations without any suggestion to purchase.

The "Allenburys"

(TRADE MARK)

Throat Pastilles

(MEDICATED)

Efficient

Palatable

The basis of the "Allenburys" Throat Pastilles is a special pâte de jujube. The pastilles are demulcent, soluble and palatable, and contain accurate amounts of pure active drugs. They dissolve slowly and uniformly, so ensuring the thorough suffusion of the mucous membrane, and the prolonged continuous direct effect of the active ingredients.

The following pastilles are largely used, and have been found from long practical experience to be very efficacious.

No. 9. Menthol, Cocaine and Red Gum
Menthol, gr. 1/20th: Cocaine, gr. 1/40th: Red Gum, gr. 2

No. 23. Eucalyptus and Red Gum
Eucalyptus, 1 minim of the Oil: Red Gum, gr. 1

No. 28. Compound Guaiacum
Guaiacum, gr. 1: Chlorate of Potash, gr. 2: Red Gum, gr. ½

No. 29. Compound Rhatany
Extract of Rhatany, gr. 2: Cocaine Hydrochlor, gr. /40th

No. 38. Chlorate of Potash, Borax and Cocaine
Chlorate of Potash, gr. 2: Borax, gr. 1: Cocaine, gr. 1/40th

No. 75. Formaldehyde and Menthol
Formaldehyde, min. 1: Menthol, gr. 1/40th

No. 77. Formaldehyde and Cinnamon Oil
Formaldehyde, min. 1: Oil Cinnamon, min. ½

1/- box of any variety, with detailed list, free to Medical Men in Great Britain.

IMPORTANT.—To ensure the supply of these active and reliable medicinal products, medical men should designate the "ALLENBURYS" Pastilles in their prescriptions.

A Consideration OF RECENT SEROLOGICAL WORK ON THE MENINGOCOCCUS.

By F. W. ANDREWES, M.D. Oxon., F.R.C.P. Lond., F.R.S.,

MAJOR, R.A.M.C. (T.); PATHOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL; PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON.

ONE of the difficulties which beset attempts at the classification of bacteria is the fact that within the limits of what, on general biological grounds, would be deemed a good "species" there are often found sub-species or races which differ only in their serological properties. In some cases the differences are slight and of little practical importance: we can employ a single strain of the typhoid bacillus for purposes of general immunisation against the disease. In other cases the differences are sharply defined, as in the case of the pneumococcus, and here a single strain seems of little value for purposes of general prophylaxis or serum treatment. But in any case the differences between such parallel strains are of a very subtle kind and are revealed only in the response of the animal body to the presence of the bacterial protein; slight differences in the latter evoke slightly different antibodies.

The property of immune serum which has chiefly been employed in defining serological races of bacteria is agglutination, though other reactions can also be used, such as fixation of complement or protective power in animals. As regards agglutination, we possess three methods of employment—namely, (1) agglutination; (2) agglutinogenic power; and (3) the power of absorbing agglutinin. Of these three methods the first is the simplest, but the third the most accurate, and of all it may be said that, while a positive result is of definite value, a negative result is not invariably conclusive.

One of the latest organisms to be submitted to close serological scrutiny is the meningococcus, because the recent outbreak of cerebro-spinal fever has brought it into prominence. The present is perhaps an opportune moment for a short review of the work accomplished in this country since the beginning of the epidemic in the winter of 1914–15, for there has just appeared an important series of papers on the subject—"Reports to the Local Government Board on Public Health and Medical Subjects (New Series, No. 114): Further Reports on Cerebro-spinal Fever."

STATE OF KNOWLEDGE AT BEGINNING OF EPIDEMIC.

Before discussing this recent work it will be convenient to consider the state of our knowledge when the epidemic commenced. When Still, in 1898, described the coccus he found in the posterior basic meningitis of infants, he was in some doubt as to its identity with the organism which Weichselbaum had described 11 years previously from cases of cerebro-spinal fever in Vienna. His chief reason for doubt was the fact that his coccus showed much more prolonged vitality on ordinary culture-media. Still's organism is now, however, universally recognised as a true meningococcus, just as the posterior basic meningitis of infants is admitted to be an endemic form of cerebro-spinal fever.

Arkwright, in 1909, was unable by serological methods to establish any specific differences between epidemic and sporadic strains of the meningococcus; the differences between individual members of each group were as great as any found between the two groups.

Serological differences amongst strains of meningococci had been established in Germany by Kutscher; he employed absorption methods, by which he was able to show marked differences amongst certain spinal and pharyngeal strains, though not of a kind to prove any sharp distinction between the spinal strains and those derived from the throats of non-contacts in Berlin. Further work in Germany was carried out on the same lines by numerous observers, largely with the object of establishing the identity or non-identity of meningococcus-like organisms from the healthy pharynx with the classical organism. Improved methods of agglutination were introduced, but these later observers were no more able than Kutscher to demonstrate constant differences between spinal and pharyngeal strains greater than existed amongst spinal strains alone. The term "pseudo-meningococcus" was, however, introduced for pharyngeal strains which could not positively be identified with the genuine organism.

The prolonged and elaborate investigations of Elser and Huntoon in the United States were disappointing in their issue. They found that a large proportion of the strains of meningococcus with which they worked were relatively inagglutinable, at least by the methods they employed; but they were able to show that such strains, though inagglutinable, might yield a serum of good agglutinating power, if not for themselves at least for certain other strains.

The first attempt at a definite grouping of meningococc was made in France by Dopter. In 1909 he recognised, in the pharynx of contacts, cocci which, while in other respects resembling the meningococcus, were not in serological conformity with that organism. He termed these "parameningococci," and two years later he was able to show that they could set up meningitis, for he found them in cases of the sporadic disease. In cases of such infection which were not benefited by ordinary antimeningococcal serum, he claimed a curative value for a serum prepared with the parameningococcus. Other French workers confirmed the distinction, and amongst parameningococci themselves indications were found of a further serological subgrouping into three varieties.

The state of our definite knowledge on this subject when the outbreak of cerebro-spinal fever in England began to assume epidemic dimensions was therefore, shortly, as follows. It was recognised—

1. That the causal agent in epidemic cerebro-spinal fever and in the endemic posterior basal meningitis of infants was the meningococcus. No cultural distinctions could be made between the cocci found in these two affections, nor could any adequate or constant serological differences be established between them.

2. That the meningococcus was divisible into certain subgroups by serological means, and notably by the absorption of agglutinin test. The number of such sub-groups was ill-defined, but they appeared to fall into two main divisions, designated by Dopter "meningococci" and "parameningococci" respectively.

3. That from the pharyngeal mucus, both of contacts and non-contacts, cocci could often be cultivated which had all the biological characters of the meningococcus. In some cases complete serological identity with that organism could be established; in other cases it could not, and some writers stigmatised such unplaced forms as "pseudo-meningococci."

RECENT RESEARCH WORK IN THIS COUNTRY.

Turning now to recent work in this country, we find it prompted by two immediate needs. The first was the provision of an adequate antiserum for treatment, since the stocks available proved of little utility. The second lay in providing means for recognising the meningococcus, especially in the pharyngeal secretions. Apart from two sets of observations carried out by Arkwright and by Ellis in France, both of which tended to support Dopter's classification of meningococci into two divisions, the work has been carried out by two independent groups of observers in this country, a military and a civil.

On behalf of the military authorities the Medical Research Committee organised a numerous band of workers all over the country, under the guidance of Lieutenant-Colonel M. H. Gordon, at the Central Cerebro-spinal Fever Laboratory at Millbank. This work has been carried out entirely amongst the military population with the special object of the prompt control of the disease. On the other hand, the Local Government Board turned the energies of its bacteriologists in the laboratories at Carlisle Place to a detailed study of the meningococcus from a more abstract point of view, but with special reference to the nature of such cocci from the pharynx of non-contacts. The material they employed was mainly from the civil population.

It is necessary to emphasise here the differences between these two sets of researches, both in their immediate objects and in the conditions under which they were carried out, for we can thus understand how certain differences have arisen in the conclusions reached.

WORK CARRIED OUT AT THE CENTRAL CEREBRO-SPINAL FEVER LABORATORY

Let us consider first the work accomplished in the Central Cerebro-spinal Fever Laboratory, the results of which have

been published in a number of papers in the *Journal of the Royal Army Medical Corps* and elsewhere, and recently in a special report issued by the Medical Research Committee.[1] The tasks undertaken by Lieutenant-Colonel Gordon and his colleagues have been arduous and very varied in character and have resulted in many advances in practical measures of diagnosis and treatment, including an improved culture-medium adapted for general use and greatly improved methods for the cure of carriers.

But I am here concerned only with one branch of their work, that relating to the serological differentiation of meningococci. This was accomplished by means of the absorption of agglutinin method applied to a large number of spinal strains. By this means Gordon separated the strains into four groups, of which two were common and two comparatively rare, though sometimes numerous in certain local outbreaks: he termed them Types I., II., III., and IV. Later experience showed that substantially all the spinal strains met with in military cases of cerebro-spinal fever could be referred to one or another of these types, which were very properly regarded as the "epidemic types" concerned in the existing outbreak. It was also shown that by mere agglutination tests, quantitatively carried out, a coccus could almost always be referred to its type, without the necessity for absorption tests.

Captain Tulloch has confirmed these results and somewhat amplified them. By employing the absorption test he has demonstrated the existence of three sub-groups in Gordon's Type II.—always the most puzzling type when reliance was placed on a single serum. Out of 104 spinal strains, fully tested, he was able to refer 101 to Gordon's four types; one of the exceptions was from a case of posterior basic meningitis.

Certain results of much practical importance followed the application of this knowledge.

1. By supplying typical strains to those engaged in making serum for therapeutic use, sera were prepared of greatly increased efficacy in treatment.

2. It was demonstrated by several workers that the type of meningococcus invariably present in the pharynx early in the disease was always the same as that found in the cerebro-spinal fluid. This not only confirms the idea that the disease is spread by means of the naso-pharyngeal secretions but also suggests that every case of cerebro-spinal fever arises in a person who is already a carrier.

3. It became possible in many cases to trace the spread of the disease by the identification of carriers bearing given types of the coccus, thus facilitating epidemiological investigations.

4. When the carriers in any locality became too numerous to deal with, a test was afforded by which the carriers of epidemic types of the coccus could be sorted out, as presumably the most dangerous, and separately treated.

It will be realised that this serological work had a direct bearing on the immediate control of the disease amongst the military population, and it was remarkable for the energy and rapidity with which it was carried out. It has been supplemented since by further experimental observations supporting the more or less specific nature of the bodily reactions against the four types of meningococci.

But although we must regard the work as well adapted for the purposes in view it must be remembered that the material which formed its basis was drawn from a limited field, and we must beware of assuming that its results convey the whole truth about the meningococcus. Gordon's conclusions are drawn almost solely from a single epidemic of the disease as it affects adults, and in his latest report he assumes an attitude which appears to me too dogmatic. He speaks of his four types as "species"—a claim which no biologist could support—and he excludes from the true meningococci those pharyngeal strains which fail to agglutinate with his four type sera, calling them "pseudo-meningococci." Here I find myself in disagreement with him.

During the past two years I have submitted the cocci from all cases of cerebro-spinal fever at St. Bartholomew's Hospital to agglutination with the four sera kindly supplied me from time to time by Major Hine at Millbank. Twenty-six cases have been in children under 5 years old, and 8 of these have agglutinated so poorly with the sera that I could not regard them as conforming fully to the types—one, indeed, failing to agglutinate at all. Although 18 of the cases did conform to one or other of the four types, I am disposed to believe that the meningococcus in the posterior basic meningitis of infants not rarely presents strains which differ from those of the epidemic form of the disease in adults. And if this is so the pharyngeal cocci from non-contacts cannot necessarily be excluded from the group of true meningococci on serological grounds alone. The most which we can legitimately assert is that such non-conforming or imperfectly conforming cocci are not examples of the epidemic types seen in adults during the present outbreak.

[1] Special Report Series, No. 3. Bacteriological Studies in the Pathology and Preventive Control of Cerebro-spinal Fever among the Forces during 1915 and 1916.

RESEARCHES OF LOCAL GOVERNMENT BOARD OBSERVERS

Let us now pass to the researches carried on by the Local Government Board observers, which have more immediately prompted this review. A year ago they presented preliminary reports based on their first year's study of the meningococcus, and especially of "non-contact" strains, in which they arrived at conclusions in a measure divergent from Gordon's. They were unable to recognise more than two main serological groups of the coccus, and these they found connected by transitional and debatable forms. So far as the number of groups is concerned the difference is apparent rather than real, for Gordon admits relationship between his Types I. and III., which are often brought down by the same serum, though unequally, and similarly between his Types II. and IV.

The present report contains what we may assume to be the final conclusions of the Local Government Board workers at the end of two years' work on the races of the meningococcus. They are embodied in six papers by as many different writers, all having as the primary object of research the relation between the cocci obtained from the spinal fluid of cerebro-spinal fever and similar organisms from the naso-pharynx, chiefly in non-contacts. In other words, the aim was to ascertain the distribution of the infecting agent amongst the population at large, and the fundamental point was to establish the relation between the pharyngeal cocci and known pathogenic strains. The problem was regarded as a pure piece of scientific research and was carried out in what may be described as an atmosphere of academic seclusion and with no need for haste. It is probable that no micro-organism has ever received a more laborious and impartial study than we find recorded in this series of papers.

Summary of Results of Investigation by Dr. Griffith.

As an example of the methods pursued by the Local Government Board workers, it will be convenient to take the paper by Dr. F. Griffith, since it is perhaps the most elaborate, and contains some interesting and original views as to the meningococcal protein viewed as an antigen.

The first step was to prepare high-titre sera from known pathogenic strains of the meningococcus ("spinal sera") and Griffith's first table shows the result of testing 66 spinal strains against six such sera. The cocci fall into two fairly well marked groups—one reacting to two of the sera, the other to the remaining four sera, but not always to an equal degree. The grouping is not quite sharp, for some of these undoubtedly pathogenic strains are indeterminate, either relatively inagglutinable with the sera employed, or agglutinating equally with sera of the two groups. Nevertheless it is sufficiently striking, and Griffith showed in a former paper that it is correlated with a difference in fermentative power—the cocci of Group I. having a preference for maltose and those of Group II. for glucose. In a general way Griffith's Group I. appears to correspond with Gordon's Types I. and III. and with the meningococcus of Dopter, while Group II. corresponds with Gordon's Types II. and IV., and with the parameningococcus of Dopter.

In Griffith's second table we find the reactions of 86 pharyngeal meningococci to the same six spinal sera. The result exhibits a similar grouping, but with the difference that representatives of Group I. are much less numerous amongst the pharyngeal than amongst the spinal strains, while indeterminate forms are far more numerous.

The next step was to prepare sera from pharyngeal strains of the meningococcus, and thus to test their agglutinogenic powers. Tables are given showing the effect of such sera upon both spinal and pharyngeal strains. The latter are found to be, on the whole, less well defined than the spinal in agglutinogenic power, as they had proved to be in agglutinability, but this indefiniteness is only what had been already observed in certain spinal strains. As a rule, the

spinal cocci were well agglutinated by the pharyngeal sera, though seldom to full titre.

Finally an elaborate series of absorption experiments is recorded, dealing with a large number of cocci and sera, both spinal and pharyngeal. For the details of these the paper itself must be consulted, for they are too numerous and complicated for summary in a short review. But they lead up to a subdivision of the two main groups into a number of sub-groups, and to a hypothesis as to the varying structure of the meningococcal antigen which is interesting and novel, and which receives considerable support from the observations described.

Put briefly, the hypothesis is as follows. The antigen of the meningococcus consists of two main components, present in unequal amount in the two main groups, each component again being liable to slight variations in structure. Group I. sera are shown to contain three agglutinins, which Griffith denominates A, B, and C, doubtless corresponding to three variations of the Group I. antigen: one, two, or three of these agglutinins may be present in any given serum. Group II. sera are similarly shown to contain at least four agglutinins. It is suggested that the meningococci of low pathogenicity, into which group a number of pharyngeal strains fall, contain antigens of simple structure belonging to Groups I. and II. in nearly equal proportions, and that in relation to the increase in pathogenicity the antigens become more and more complex, culminating in the epidemic types which have recently prevailed amongst spinal strains. All this is speculation, maybe, but it is speculation based on careful experiment, for which chapter and verse are fully given, and which offers a reasonable explanation of the observed facts. The final conclusion at which Dr. Griffith arrives is that all the forms, whether from the pharynx or meninges, which can be culturally identified with the meningococcus, are to be regarded as that organism in a biological sense.

Conclusions Reached by Other Investigators.

These conclusions are generally supported in the independent paper written by Dr. W. M. Scott. This paper is based on the examination of 60 strains of spinal and 71 strains of pharyngeal meningococci, distinct from those which were the subject of Dr. Griffith's work. Nineteen sera were produced from various spinal and pharyngeal strains, and were employed on much the same lines as Dr. Griffith had followed, the absorption test being largely used. The result was a subdivision into two main groups, but, perhaps because he worked with a different set of cocci and sera, the sub-grouping reached by Dr. Scott is not identical with that of Dr. Griffith. He found that in Group I. there was a main group and at least five subsidiary groups, and in Group II. a main group and at least two subsidiary groups. These differences are not surprising when it is considered that the numbers of strains studied were limited and the possible variations of the meningococcal antigen practically infinite. Dr. Scott has not indulged in the constructive speculations which form so interesting a feature of Dr. Griffith's report, but his work bears the same stamp of patient thoroughness, and his final conclusion as to the specific identity of spinal and pharyngeal meningococci is the same.

Although space fails for a review of the papers by Dr. Ponder and Dr. Lewis, it may be said that they are in complete accord in their general conclusions with those of the previous papers; Dr. Nabarro does not deal with the serological side of the question. By no means the least interesting paper in the report is that written by Dr. Eastwood, who contributes a philosophical essay on the whole subject of the absorption of agglutinin test and the division of bacterial species into serological sub-groups—an essay well worth careful study on account of his acute criticisms on the subject. He raises the question whether the differences between related antigens may not depend upon stereo-chemical configuration, and is disposed to argue in favour of this: it is an interesting suggestion, but one which at the present time seems insusceptible either of proof or disproof. As regards the unity of the meningococcus Dr. Eastwood sums up very definitely: he holds that cultural tests, adequately performed, suffice for the diagnosis of the species, though he is far from denying the utility of serological study for special purposes.

CAUSE OF DIVERGENT VIEWS.

From the foregoing short summary it will be apparent that the conclusions of the different Local Government Board workers are opposed to the views which Lieutenant-Colonel Gordon has recently expressed as to the delimitation of the meningococcus as a species. And I am bound to confess that their picture of the races comprised within its limits is one which appeals to me, as a biologist and evolutionist, more than Gordon's conception.

It is not difficult to see how the difference in opinion has come about: indeed, it seems the natural outcome of the different fields of work. If there is any truth in Griffith's view of relatively unspecialised races of the coccus often found in the normal pharynx, from which have arisen the pathogenic types, with their higher antigenic complexity, seen in the epidemic form of cerebro-spinal fever, it almost necessarily follows that the observer whose purview is limited, by the nature of his material, to the most specialised and virulent types, will arrive at different conclusions from the man who works largely with the unspecialised as well as with the specialised forms of the coccus. Of the two, the latter seems to me the more likely to be correct in his generalisations because his point of view is the wider. Gordon's work, on the other hand, is probably the better adapted for measures designed to control an epidemic; he has limited himself to his four "epidemic types" and very properly concentrated his attention on these as the immediately dangerous cocci. He only overshoots the mark when he elevates his types to the rank of species and seeks to exclude from the conception "meningococcus" the less virulent races which form the rank and file.

Two years ago Professor Bulloch, Professor Hewlett, and myself were invited by the Medical Research Committee to report upon the observations on cerebro-spinal fever made in various laboratories during the first year of the war. In our report we suggested that the meningococcus, widely spread as a saprophyte in the human naso-pharynx, was in non-epidemic times of insufficient virulence to attack any but the most susceptible of the population (posterior basic meningitis of infants), but that increase of virulence might enable the coccus to attack young adults also, and give rise to the epidemic form of the disease. At the time we put forward this suggestion we felt that it was an inference only, unsupported by any sufficient basis of observation or experimental fact. It is a great satisfaction to me to find, in the work recorded in this report to the Local Government Board, and especially in Dr. Griffith's paper, an analysis of the different races of the meningococcus which supplies the very basis of fact required to support the opinions we then ventured to put forward.

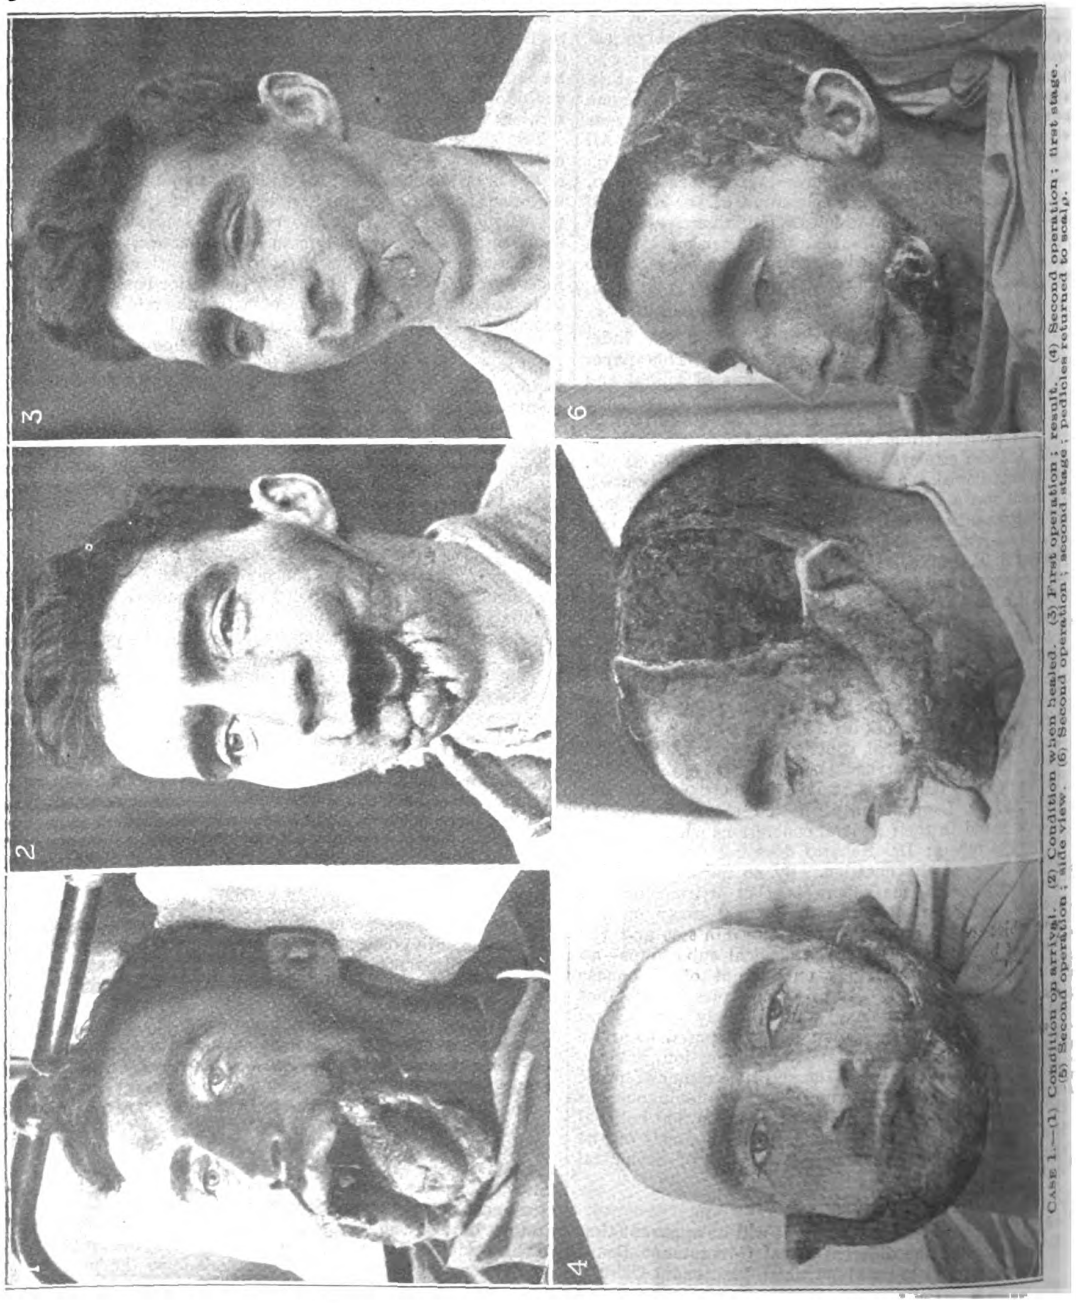
A WORKING HYPOTHESIS.

The picture which is left on my mind, on consideration of all the serological work which I have attempted to review, is a definite, though not a very simple one, and may, I think, be accepted as a fair working hypothesis in the present state of our knowledge. It is as follows.

The meningococcus is a single, definite species, recognisable by its cultural characters and fermentative reactions, and widely spread as a pharyngeal saprophyte—often a transitory one. In its most primitive form it is a relatively harmless organism, but even at this stage its protein presents two antigenic components. These two components are rarely evenly balanced, and from a serological point of view there emerge two primary races of the coccus—Group I. and Group II.—which correspond to the meningococcus and parameningococcus. The latter term is a misnomer since both are true meningococci. The term pseudo-meningococcus is equally erroneous; so far as it has any meaning it signifies a meningococcus of primitive type and low pathogenic power.

Under ordinary circumstances the bulk of the saprophytic meningococci of the pharynx are of this low type and mostly fall under Group II., though some are indeterminate. Even in non-epidemic times certain strains of these simple cocci possess sufficient virulence to attack the very young: hence we always have with us sporadic cases of cerebro-spinal meningitis.

For unknown reasons there is a tendency at times for certain strains to increase in virulence, and this is accompanied by an increased complexity in the structure of the antigen, taking different forms in different strains; we do not know whether the increased complexity is due to the increased virulence or vice versâ. The phenomenon is seen in both primary groups, but, on the whole, more in Group I. than Group II., so that, whereas in the less virulent forms Group II. is the commoner, in the more highly virulent ones the proportions



become more equal. When cerebro-spinal fever attains epidemic prevalence the virulent strains concerned stand out with relative but not absolute distinctness. The strains in question are possibly different in different epidemics: in the recent outbreak in this country four such strains are recognisable, two belonging to Group I. and two to Group II. The serological recognition of such epidemic types is of manifest importance, both for the preparation of suitable therapeutic sera and for the sorting out of the more dangerous types of carrier.

Such a conception as this appears in harmony with the observed facts in the recent epidemic, and serves to reconcile the apparent discrepancies in the results put forward by different workers on the subject.

TWO CASES ILLUSTRATING PLASTIC AND DENTAL TREATMENT.

BY H. D. GILLIES, F.R.C.S. ENG.,
MAJOR, R.A.M.C.: PLASTIC SURGEON TO THE QUEEN'S HOSPITAL, FROGNAL, SIDCUP.

CASE 1. *Re-formation of the chin and lower lip by double-pedicled bridge flaps and cartilage graft.*—This is shown as an attempt at restoration in that not uncommon class of gunshot wound of the jaw in which the whole body of the mandible and the soft overlying tissues have been blown away *en masse*. The photograph of this patient, taken soon after admission, sufficiently explains the extent of the lesion (*Fig.* 1, Case 1). It is an interesting point to note that this gallant fellow walked several miles to the dressing station on July 14th, 1916, during the battle of the Somme, and this very feat of endurance, maintaining, as it did, the upright position, may have prevented an emergency tracheotomy or even a worse fate. The loss of the lower lip and tissues of the chin is complete, while the amount of mandible remaining is represented by the thinned and atrophied

CASE 1.—(1) Condition on arrival. (2) Condition when healed. (3) First operation; result. (4) Second operation; first stage. (5) Second operation; side view. (6) Second operation; second stage; pedicles returned to mouth.

ascending ramus of the right side, and by the ascending ramus, angle, and one molar tooth on the left. The condition in January, 1917, after the healing process was complete and the general condition more satisfactory, is shown in Fig. 2 (Case 1).

At this stage the first operation, which took place on Feb. 27th, 1917, was performed under chloroform-oxygen anæsthesia in the sitting position, administered by Lieutenant R. Wade, at the Cambridge Hospital, Aldershot. The main features of the operation were the freeing of the tongue and the making of the flap which formed the basis of a new lip. The result, as far as it went, was satisfactory, as shown in Fig. 3 (Case 1), but the absence of the mental prominence as well as the loss of functions were left to be dealt with until a later stage.

A serious attempt to bulge out the new "lip" by traction from a head-piece was madein conjunction with Captain W. Kelsey Fry, M C., at the time of this operation, but it was badly tolerated and the result was not gratifying. In view of the general shortage of tissue, plastic flaps from the neck or cheek were not indicated, and in view of the success of the double-pedicled embedded flaps and of the experience one has had of single-pedicled bridge flaps it occurred to me that the employment of a double-pedicled bridge flap from the scalp would meet the case without fear of the blood-supply. By a bridge flap is meant one in which the pedicle lies over healthy skin, is divided from the grafted terminal portion after about ten days, and is then replaced into its original position. The double-bridge flap, though I believe original, is merely the logical development of double-pedicle embedded and single-pedicle bridge flaps, and it combines the advantages of a double blood-supply and of the provision of a flap well distant from the lesion.

In this particular operation, which took place on Sept. 20th, 1917, at the Queen's Hospital, Sidcup, Captain J. L. Aymard and Lieutenant G. C. Birt assisting, in which ether-oil was given by the rectal method (Lieutenant R. Wade), the flap stretched from ear to ear to the other across the vertex and was about 3 inches in width. (See Figs. 4 and 5, Case 1). Before bringing this into position

CASE 2.—(1 and 2) Condition on admission. (3) Adjustable intranasal support carried from a metal cap splint cemented to the upper teeth. (4) Improvement obtained by operation and insertion of nasal splint. (5 and 6) Result of insertion of cartilage graft from rib. Taken three months after operation.

the skin below the buccal opening was raised by incision and dissection and laid on the upper surface of a large osteo-cartilaginous graft from the seventh rib. This measured some 6 inches along its long convex border and was the shape of a boomerang; it included about 1 inch of the bony portion of the rib and was fixed by iron wire into the remains of the jaw, bone to bone on the left side and cartilage to bone on the right, being fixed so that the point of maximum convexity of the cartilage became the prominence of the chin. The large scalp flap was then swung over the face into position so that it covered the upper, lower, and lateral aspects of the new "jaw," and sutured to the surrounding skin edges. The pedicles were cut on the eleventh day and returned to the scalp (Fig. 6, Case 1); the new blood-supply of the grafted portion being satisfactory, there was no question of gangrene.

Many causes operated against asepsis, of which the more obvious were: (1) the length of operation; (2) the difficulty of sealing off the junction of the pedicle and the embedded portion; and (3) the very strong growth of hair on the flap. Discharge appeared at the lower border of the flap on the fifth day, and has continued.

I must own that in planning this operation it was not expected that a good functional result would accrue, but some degree of mastication is yet possible where there was none, and the gain to the patient of having a chin and a full beard is almost certainly permanent. The secondary disability is a bare area on the top of the scalp, which is being epithelialised.

In criticising this procedure I feel it would be better to either insert a piece of metal or celluloid at the time the scalp flap is brought down, to be replaced later by an osteo-cartilaginous graft under more aseptic conditions, or else to embed the graft in two halves in the scalp some six weeks before it is swung down. In this event the graft, at a later stage, could be joined in the middle and to the remains of the jaw.

There still remains the freeing of the lip to be done, which is best achieved by an epithelial inlay as advocated by Esser. The present condition of the case is as shown in Fig. 6 (Case 1), and although there is a discharge it is diminishing, and, in view of past experience, it is reasonable to expect the process to cease and the appearance to be maintained. Later note: Discharge almost ceased.

CASE 2. *Restoration of the nose by dental splint and cartilage graft.*—Wounded on 20/12/16. The condition on admission, nine days later, to the Cambridge Hospital, Aldershot, is shown in Figs. 1 and 2 (Case 2); the anterior part of the septum, with portions of both alæ, having been shot away, a considerable flattening of the nose resulted.

First operation, 15/1/17: The flattened portions having been freed of all their adhesions under chloroform, I inserted the apparatus shown in Fig. 3 (Case 2) (drawn by Professor H. Tonks), made by Captain L. A. B. King and staff. This was continuously worn by the patient for seven weeks and produced a very considerable improvement, as shown in Fig. 4 (Case 2). Figs. 5 and 6 (Case 2) show the later and permanent result of the insertion of a cartilage graft 3 inches in length, taken from the eighth rib, to raise and support the lower part of the nose. The cartilage was inserted in two portions through the columella; the longer portion was pushed in beneath the skin to form the bridge, while a shorter piece was embedded down the columella towards the maxilla so as to support the tip of the nose. Plastic re-suture of the alæ to give symmetrical appearance was carried out at the same operation.

To Captain Kelsey Fry belongs the credit of giving the nasal splint a prolonged trial.

THE LIGHTING OF MOTOR CYCLES.—With the prohibition of the sale of calcium carbide acetylene lamps are out of the question, whilst electric lighting outfits cannot be readily purchased and oil lamps are not ideal for use on a motor cycle. The Auto-Cycle Union will investigate and report upon applications from medical practitioners for calcium carbide, with the approval of the Ministry of Munitions. Permits will be issued under Para. 4 of the Order of Sept. 24th, 1917, and applications will receive consideration within the limits of the supply of carbide available. Medical men should apply to the Secretary, Auto-Cycle Union, 83, Pall Mall, S.W.1, for forms on which to apply for permits.

A FEW NOTES

ON THE TREATMENT OF GUNSHOT WOUNDS OF THE MANDIBLE AND MAXILLA.

BY W. KELSEY FRY, M.C., M.R.C.S., L.D.S.

TEMPORARY CAPTAIN, R.A.M.C.; OFFICER IN CHARGE, DENTAL DEPARTMENT, QUEEN'S HOSPITAL, SIDCUP.

(*From the Dental Department, Queen's Hospital, Frognal, Sidcup.*)

THE work of this department is very varied, but it may be taken roughly that 75 per cent. of the patients admitted have fractured mandibles with or without fracture of the maxilla, a further 10 per cent. have fractures of the maxilla that require dental treatment, and the remaining 15 per cent. are purely plastic cases.

Fracture of the Mandible.

The routine treatment of this injury will now be described. As soon as possible the patient is sent to the radiographic department in order that skiagrams may be taken to demonstrate the situation and extent of the injury to the bone. For this purpose an antero-posterior in addition to a right or left special view is always taken.

In obtaining the antero-posterior view the patient's face is, of course, always next to the photographic plate. A careful examination of such a skiagram will determine any lack of symmetry with regard to the mandible, and will show a break in the continuity of the bone should it be present; the amount of displacement can also be detected with ease. If a fracture of the coronoid process or neck of condyle is suspected it is best to take the skiagram with the mouth open.

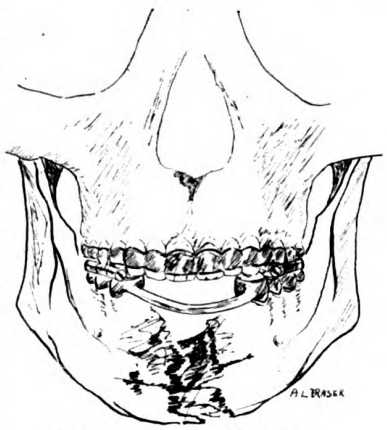
When a fracture is present in the regions of the horizontal and ascending rami a lateral view is always necessary, as the rays must be directed as far as possible at right angles to their lateral surface, and in order to obtain precise information care must be taken to avoid in the picture overlapping of the two lateral halves.

It is very important to repeat these lateral views at intervals of a month or six weeks in exactly the same position, so that any change in the position of the fragments can be detected and estimate of the progress determined.

The following points to be noted in the skiagrams thus obtained are: (1) The teeth involved in the fractured area and those likely to be involved at a later period; (2) the amount of bone lost; (3) type of displacement; (4) the presence of foreign bodies, which include not only metal fragments, but displaced teeth.

Having obtained in this way information regarding the relationship of the fracture to the teeth, the question of their extraction is now considered. When the wound is very septic, as is generally the case, free extraction is the rule—that is to say, any tooth which is in the line of fracture or likely to become involved by absorption of the surrounding bone is removed. Lines of fracture are open pathways for the spreading of an infective process, and should they be in proximity to the periodontal membrane a secondary inflammatory condition of the latter is bound to follow in the very area in which it is hoped new bone will be formed. More conservative treatment can be adopted in circumstances where the wound is not likely to be much infected—such as fractures occurring in civil practice, where violence is less extreme when the blow has been inflicted by comparatively blunt objects. Such cases are sometimes met in military practice—horse kick, injuries from dug-out falling in, &c.

Sometimes, however, a tooth is retained on the posterior fragment of the mandible which at first examination would require to be removed, but it must be remembered that it is extremely important to have a molar tooth left for splinting purposes, and the benefit to be gained by retaining it, even for a time, outweighs the septic risks of keeping it. Skiagrams are taken at intervals while patient is under treatment, and the condition of the area around the tooth and the progress of repair are carefully observed.



At the time of extraction of the teeth drainage is always established. A piece of rubber tubing is placed between the ends of the bone and brought into the submaxillary or submental region of the neck. Should the position of the

wound in the soft parts not be suitable for this purpose a fresh counter-opening is made. This procedure is especially useful for middle-line fractures.

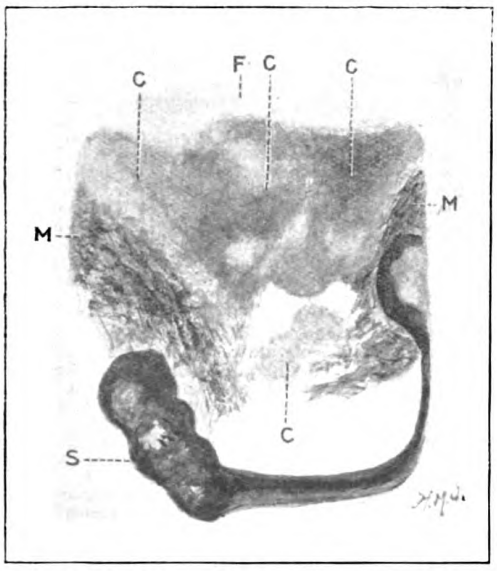
The drainage-tubes are left in from 14 to 21 days, being gradually withdrawn after about seven days.

No bone is removed at time of operation, except that which is very loose and obviously necrotic, in the hope that some osteogenetic cells may be still alive and later on contribute to the formation of callus. This is specially noticeable in the symphysis region, where quite small loose pieces of bone form a large amount of callus provided the drainage is adequate.

FIG. 1.

Splints. Front aspect in position.

FIG. 1A.



Splints shown in detail. (Reduced to half size.)

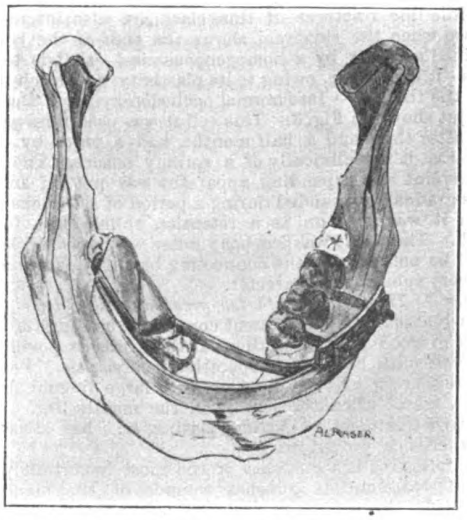
Impressions of the teeth are now taken for making the splints. This is often a very difficult undertaking, but small shallow trays with the use of plaster-of-Paris will often give satisfaction. I have recently taken my impressions after the patient has had the teeth extracted, and while he is still under the influence of the anæsthetic. In the latter case it is best to use dental composition, as it hardens very quickly.

While the splints are being made the broken fragments of the mandible are put at rest by ligaturing the teeth to the maxilla with grass line and brass ligature wire. The former, which was brought to my notice by Lieutenant H. C. Malleson, R.A.M.C., has proved very useful for this purpose. The one disadvantage is that it is difficult sometimes to pass it between the necessary teeth.

I have overcome this by using a surgeon's curved plastic needle, which can be easily introduced between the necks of the required teeth without injuring the marginal tissues.

FIG. 2.

Drawing of skiagram of middle fracture of mandible three months after injury. C, callus; F, floor of mouth; M, mandible; S, splint.



At this stage a case is classified into one of three classes: (1) Those cases which should get primary bony union in normal occlusion; (2) those cases in which primary bony union is doubtful; (3) those cases in which it is certain that no functional useful primary union can be got owing to too great a loss of bone.

Class 1. Cases in which primary bony union in normal occlusion is expected.—These cases are splinted into normal occlusion. Upper and lower capped cast splints are most generally used. It is very seldom that a lower splint alone is used even for simple middle line fractures as the front teeth generally have to be extracted. In these cases the fulcrum of the splint is found to be too far back, and in spite of a firm connecting bar, slight movement is present which has been known to account for the non-union of these fractures.

The most common type of splint which is used is shown in Fig. 1. These are retained from two to five months, varying with the progress of the case. The splints are so constructed that it is possible to open the mouth at any time to remove sequestra, &c.

There is one type of fracture which often presents considerable difficulty—i.e., fractures of the symphysis with a

FIG. 3.

fair amount of comminution. It is found on removing a splint after a period of about three months a condition of the fragments exists which on casual examination would lead one to suspect that complete bony union had taken place. On careful examination, however, a slight springiness will sometimes be detected. If this is the case, in my experience it is not likely that the complete consolidation will take place if the splint is removed. This union is really only callus, which is known to be of a plastic nature, and the patient will bite the two lateral fragments inwards in a very short time. This type of case is very difficult to radiograph. The best results have been obtained by Lieutenant H. M. Johnston, R.A.M.C., by the use of small plates of aluminium cassettes placed inside the mouth. The skiagrams thus obtained require very careful reading.

Fig. 2 shows the mass of tissue joining the two ends of the bone is of a homogeneous appearance—that is to say, it consists of callus only. Repeated skiagrams of these cases should be taken until definite bony spicules can be seen running through the homogeneous mass.

Class 2. Fracture of mandible with a fairly large loss of bone; prospect of obtaining primary bony union doubtful.—In these cases the patient must be given every chance of getting primary bony union, and in fractures of the angle the anterior fragment must be swung over to help fill up the gap. Nature also helps by swinging forward the posterior fragment. In middle-line fractures the two sides must be approximated. In these positions the jaws must be splinted for a varying period and repeated skiagrams taken. If large pieces of necrosed bone have exfoliated and no chance of union is observed, the case is then treated as in Class 3. If the case is seen to be progressing favourably the splints are left until some bony union has taken place, by which time, by extracting one or two upper teeth on the affected side, the jaw can be swung back into its normal position. On the other hand, if the jaw has been swung over too far and cannot be swung back the bone is in a better condition for a bone-graft, because the freshly cut ends are preferable to the sclerosed ends of the ununited fragments.

FIG. 4.

Kingsley's splint in position.

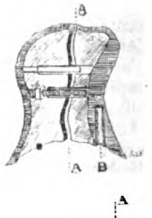
Surgically, however, a difficulty may arise in this latter procedure, the mucous membrane of the mouth possibly being perforated whilst stretching the two parts. In such a case the fragments must be separated and brought as far as possible into normal occlusion and the bone-graft operation postponed to a later date.

Middle-line fractures of this class are also interesting, because when the skiagram shows the ends of the bone to be joined together by a homogeneous mass—that is to say, callus—it is possible, owing to its plasticity, to stretch it and bring the fragments into normal occlusion by using the type of splint shown in Fig. 3. This splint was used for a patient who, after three and a half months, had a union by callus only—i.e., it was clinically of a springy nature. The combined splint and expanding apparatus was put on and the callus gradually expanded during a period of six weeks, after which it was kept on as a retention splint for a further month. The result was firm bony union with good occlusion. It will be noticed that the connecting bar of this splint was of a very substantial character.

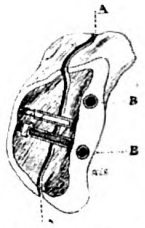
Class 3. Those cases with too great a loss of bone to get primary union.—The treatment consists in holding the fragments in good position with as little strain as possible on the teeth until bone graft operation is advisable. For this purpose a lower cast tin denture with large lingual flanges is very useful when the loss is in the middle line. Early operative treatment by wiring, plating, &c., has always, in my experience, proved useless.

The following is a summary of the most important points in the treatment of gunshot wounds of the mandible: (1) Getting the patient early; (2) freeing the mouth of all septic teeth and teeth involved or likely to be in the fractured area; (3) establishing good downward drainage as early as possible; (4) not removing any loose bone unless obviously necrotic; (5) reduce displacement as soon as possible, especially the open bite; (6) absolute immobility of the fractured ends for a long period; (7) thorough exposure and removal of sequestra; (8) when the union is thought to be delayed interference by surgical means should be considered; and (9) stimulating the growth of callus by massage and high-frequency treatment.

Fracture of the Maxilla.



There is only one class of these cases and they are treated with success in the following way: (1) Free extraction of septic teeth and teeth involved in fractured area; (2) early suturing of soft parts when possible; (3) good drainage; (4) leaving all loose bone to exfoliate itself; (5) supporting the maxilla with a vulcanite "Kingsley" splint which has been perforated to assist drainage. The splint is held up by elastics to a head net or plaster-of-Paris bandage around the head. (Fig. 4.) In a very badly fractured maxilla in high position care has to be taken not to press upwards too much in case the optic nerve is pressed upon.



In treating old gunshot wounds of the maxilla numerous difficulties present themselves and various appliances differing in every case with the degree of loss are used. The following is an example:—

The patient was wounded 18/8/16, and was admitted into this hospital 10/3/17. On examination it was found that he had got an old gunshot wound in the face with large loss of the maxilla and nasal structure, and loss of both eyes. The hard palate was entirely lost except for a small part which included the two posterior tuberosities with the intervening part of the palate. Both antra were widely opened owing to the absence of the nasal and anterior walls. The soft tissues of the lip and nose were adherent to the small remaining part of the palate as shown in Fig. 5.

The case was seen by Major H. D. Gillies, R.A.M.C., who decided to free the soft tissues from the small remaining part of the palate. Major Gillies operated; preliminary laryngotomy and anæsthetic given through laryngotomy tube. A knife was inserted behind the upper lip, and the line of attachment of the soft parts both to the hard palate and laterally to the remains of the superior maxilla was divided in a vertical direction until the level of the eye-sockets was reached. The soft tissues were then stretched forward.

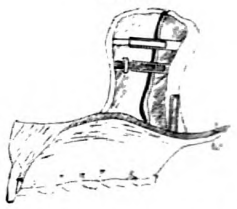


FIG. 6.

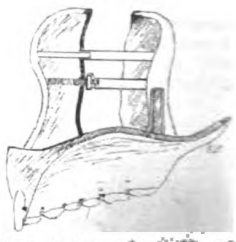


Mould. A—A, line of division of mould. B—B, sockets for split pins on denture. (Reduced to half size.)

FIG. 7.

Mould with denture in position before expansion.

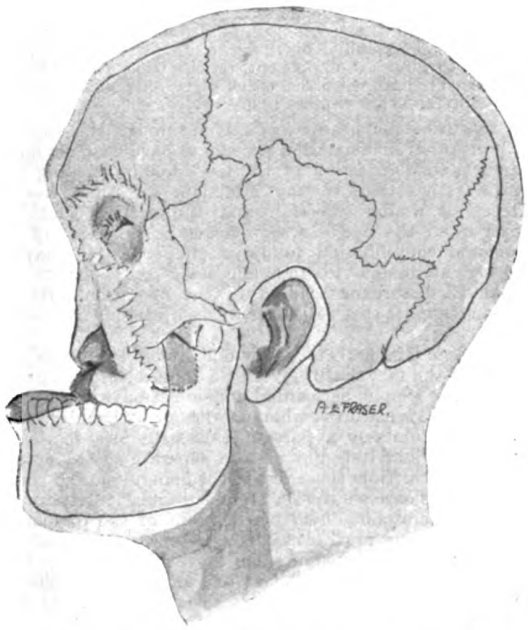
FIG. 8.

New position of mould and denture after expansion.

At this stage the case was taken over by the dental department for the soft parts to be kept in the new position. While still under the anæsthetic dental composition was forced up into the gap made and left to harden. When hardened it was removed and the impression used for making the necessary permanent apparatus. In the meantime another piece of composition was inserted into the gap and left in position to hold the soft parts out while the apparatus was being made.

The type of apparatus made is shown in Figs. 6, 7, 8.

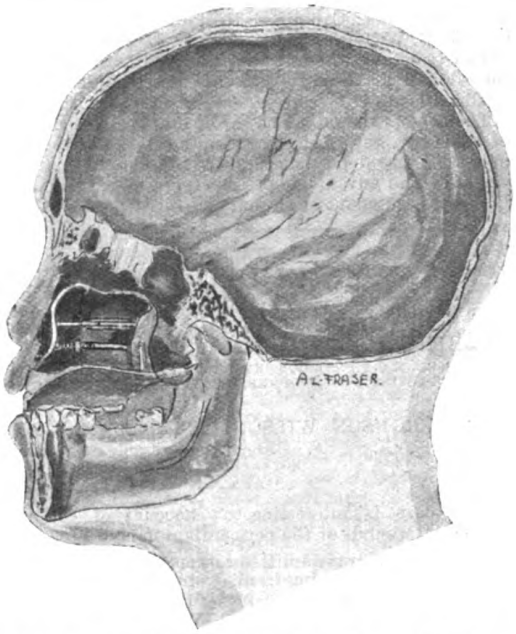
A hollowed-out piece of vulcanite was made to fill the gap. This had a nut and bolt arrangement which enabled the front part to be pushed forward when required after the mould had been divided along the line (A—A, Fig. 6).



A denture was then attached to this mould by two split pins which fitted into the posterior part of the mould, which had been specially thickened for this purpose (B—B, Fig. 6).

During a period of two or three weeks the upper part of the apparatus was gradually brought forward to the position shown in Fig. 8, which gave the patient the best cosmetic effect.

In order to maintain this position permanently and at the same time to prevent the soft tissues encroaching into the gap the interval was filled up with vulcanite, a procedure which occupied about four hours.



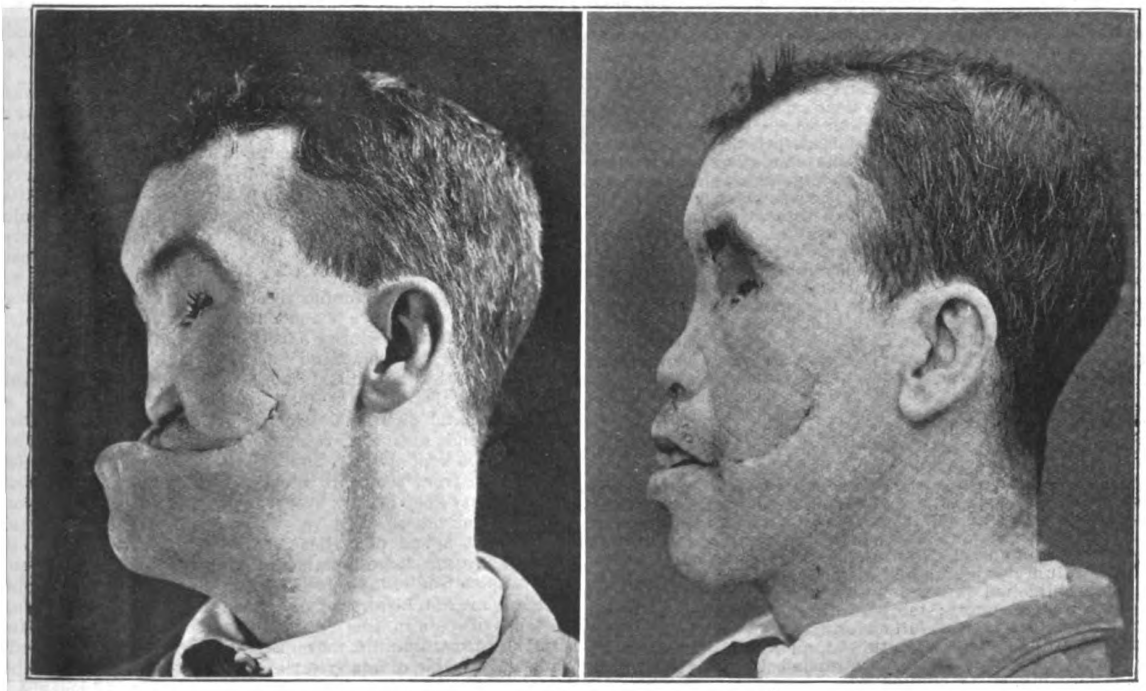
When we attempted to replace the mould we were surprised to find that this was impossible. The scar tissue had contracted so much during the short time that it was necessary to administer nitrous oxide gas and forcibly stretch the soft parts (the apparatus had previously been

FIG. 5.

Shows the portion of maxilla lost and the soft tissues adhere .t.

FIG. 9.

Mould and denture *in situ* after gap has been filled with vulcanite.



removed twice daily by the patient himself for the purpose of cleaning, and no difficulty had been experienced). The denture was now remade to fit the mould accurately in its new and permanent position. (Fig. 9.) The patient now is able to eat a fair diet and the cosmetic effect is greatly improved. Figs. 10 A and 10 B show the patient before and after operation and dental treatment.

The diagrams accompanying this article have been drawn by Captain A. L. Fraser, dental surgeon. In addition, I should like to acknowledge the great help both in general principles and in mechanical details that I have received from one and all of the staff.

When a group of keen dental men are working for the same end—the benefit of the patient—it is obvious that the work on any one case is the product of ideas of the whole staff. The mechanical work carried out by one dental surgeon in any particular case is the outcome of the general experience of the department both in this present home and as it

FIG. 10 A.

FIG. 10 B.

Before treatment.

After operation and dental treatment.

used to be at the Cambridge Hospital, Aldershot. In this connexion I should like to mention the early work done by Captain L. B. King whilst at Aldershot, and especially the present workers: Captain E. G. Robertson, Captain A. Jupp, Captain E. W. Lowe, and Captain A. L. Fraser.

The general control of the fractured jaw cases, both in their dental and their plastic stages, is under the doubly-qualified medical officers who are in charge of the cases.

The combined dental and medical knowledge of this type of officer is rightly held by the authorities to be indispensable to a jaw department, and at present, in this capacity, we have the advantage of the services of Captain C. F. Rumsey, Lieutenant Malleson, and Lieutenant G. C. Birt.

A CASE OF TRAUMATIC PERICARDITIS DUE TO A NEEDLE.

BY ARTHUR J. HALL, M.A., M.D.CAMB., F.R.C.P.LOND.,
MAJOR, R.A.M.C. T.F.; SENIOR PHYSICIAN, SHEFFIELD ROYAL HOSPITAL; PROFESSOR OF MEDICINE, UNIVERSITY OF SHEFFIELD;
AND
J. B. FERGUSON WILSON, M.S. LOND., F.R.C.S. ENG.,
CAPTAIN, R.A.M.C. T.F.; SENIOR ASSISTANT SURGEON, SHEFFIELD ROYAL HOSPITAL.

THIS case is interesting on account of the rarity of accidental wounds of the pericardium in civil life.

A girl aged 12 was admitted to the Sheffield Royal Hospital on August 21st suffering from dyspnœa. Her history was as follows. On the 16th she picked up an old rusty sewing needle which she found in the street and pinned it in the front of her blouse. When she got home she vomited twice and felt poorly. She also had some pain in her chest, and her mother found a mark on the chest, together with the broken end of the needle sticking in the blouse. The child thinks that the needle must have run into her chest whilst she was leaning against a wall, but she did not feel any pain at the time and was quite unaware of what had happened. As her symptoms did not improve she was brought to hospital five days later.

When seen the same evening the child was lying propped up in bed. The respiration was frequent and shallow, alæ nasi dilating; slight pyrexia. She did not complain of pain anywhere, and, in fact, the absence of subjective distress was a striking feature throughout. On examining the chest the cardiac dullness was found much enlarged; it extended for 1½ inches to the right of the sternum and as far as the anterior axillary line to the left; upwards to the first intercostal space. The impulse could not be felt; the heart sounds were very faint. There was a loud double pericardial friction over the sternum and to the left. The point of entry of the needle was visible as a small punctate scar situated at the left edge of the sternum, where it is joined by the lower border of the fourth left costal cartilage. It seemed quite healthy; there was no pus. A radiogram taken from the front showed the portion of needle lying almost in the middle line, a little to the left, at a level corresponding to the site of entry. As seen in this plane it was about ¾ inch long. The plate also showed a large heart shadow, due to the pericardial effusion. The pulse was 120–130.

As the child did not seem in any immediate danger it was agreed not to attempt the removal of the needle until a further radiogram had been taken giving a side view, and then to proceed according to what it showed. On the next day the lateral radiogram showed the needle pointing almost horizontally backwards. It was about ¾ inch long, one half of it being in or alongside the sternum, the remainder projecting into the thorax. The physical signs were the same as on the previous day, and operation was decided upon. As the surface wound seemed to be slightly to the left of the sternum, it was thought that the needle had probably gone through the fourth left space. An incision was therefore made at this level, but no trace of the needle or its track was found. The cartilage of the fifth left rib was then cut through and turned outwards, but still without result. On passing the finger mesially behind the sternum the point of the needle was felt projecting backwards, and by means of a blunt instrument was easily pushed forwards out of the front of the sternum through its channel of entry. The wound was then closed. Neither pericardium nor pleura had been opened.

The child had rather a restless night, with a good deal of cough and dyspnœa; temperature slightly raised. It was not possible to make a full examination of the left chest on the following day owing to the wound and dressings, but the dullness to the right of the sternum had obviously diminished considerably. The friction sounds were also less audible. There was, however, a large extension of dullness up to the left clavicle, and bronchial breathing over the left upper front. On the 24th the child was much better, the cardiac dullness was smaller, the friction sounds were rather more to the left, and the area of lung dullness and bronchial breathing had extended downwards. After this she made rapid improvement, and on Sept. 1st the friction sounds had disappeared; there were also signs of resolution in the left lung. She made a complete recovery.

In this case the needle was driven through the sternum and pericardial inflammation appears to have been set up by the mechanical irritation of the needle-point sticking into the sac rather than to any infection, for there was no evidence of wound infection and the effusion subsided quickly when the needle was removed. The cause of the pneumonic consolidation following the operation may be variously attributed to the effect of ether or to the mechanical disturbance caused by the operation. Its site of origin suggests that the latter was at least a contributing cause.

Remarks by Major HALL.—The chief interest in this case consists in the fact that it gives us a picture of the clinical effects of a simple pericardial inflammation without anything else. Pericarditis, whether with or without effusion, is, as a rule, merely a part of some general infection or fatal disease, and it is not easy to separate the symptoms due to the local from those due to the general morbid condition. In this case we have a simple traumatic irritant, the mechanical scratching by a needle-point of the pericardial walls, and if any organisms were present and played any part in producing inflammation they were, at any rate, introduced directly from without and not from the general blood-stream or from neighbouring diseased areas. It is, in fact, more like a simple laboratory experiment than a pericarditis of disease such as we are accustomed to meet with in clinical work. The general impression which it gives is that such a simple pericardial inflammation is a much less serious and formidable condition than one would be led by previous experience to expect.

The cardinal symptoms of a pericarditis are (1) pain, usually over or near the præcordium, sometimes very severe; (2) dyspnœa, and other symptoms of cardiac embarrassment; and (3) nervous complications, restlessness, insomnia, vomiting, and, at times, delirium, varying in degree, and at times associated with convulsions or ending in coma. In some cases it has been noted that some or even all of these symptoms are slight or even absent, and various reasons have been given to explain this anomaly. If one may judge by the case here recorded it seems rather that mildness or absence of severe symptoms is the natural history of a pericardial inflammation alone, and that the severe symptoms often observed are due not to the pericarditis but to other associated troubles.

In this case pain over the præcordium or elsewhere was absent throughout. There was certainly none during the child's stay in hospital, and, according to her own repeated statement, there was none previously. Cases without pain have been often recorded, and one knows that this is particularly so in young children; also that in cases of pericarditis occurring as a terminal or pre-terminal event in chronic disease the actual existence of this complication has only been discovered at autopsy. This absence of pain is rather surprising when one thinks of the intensity of pain so commonly present in similar affections of the neighbouring pleura. Possibly there is a mechanical explanation of this. Even the pain of pleurisy varies considerably, according to the part of the membrane affected, and it is a common experience that an apical pneumonia, with its attendant pleurisy, is less painful than one at the base, whilst a diaphragmatic pleurisy is exceedingly painful. This difference depends upon the extent to which the acutely inflamed area can be kept at rest, and this is greater the further the trouble is from the more mobile lower parts of the chest, where every deep breath, every cough, and every contraction of the trunk muscles involves movement of the affected parts. That most apical pleurisies must be painless or nearly so is shown by the large number of cadavers in which extensive apical adhesions are found, and yet there is no record in the history of the case of any corresponding attacks of pain in this region having occurred during life. In the pericardium the movements of the heart are limited and not capable of much variation in extent, so long as the patient is at rest, nor do respiratory movements of the chest

wall alter the position of the sac to any great extent. Thus, on the whole, the factor which brings about pain in a pleurisy—namely, increased movement—occurs less in pericarditis. It may therefore be assumed that in a simple pericardial inflammation, due to mechanical causes, and with no complications, pain is not an essential characteristic.

The second cardinal symptom, described in the text-books, is dyspnœa with cardiac embarrassment. This is usually explained on mechanical grounds, and seems natural and reasonable. As the fluid increases in amount the pressure on the heart increases, and the compression of the great afferent vessels at the back and lower part of the sac must also become greater. But it has been noted that in some cases the sac can contain extremely large quantities of fluid without very much inconvenience. This has been explained by saying that the amount which the sac can contain without causing distress depends on the rate at which the fluid accumulates; if it is a slow and gradual process the sac has time to become distended, while if it is formed quickly the distress is urgent. Everything depends upon how the terms "slow" and "quick" in this sense are interpreted. What is a quick formation of fluid in a pericarditis? Pathologists state that the first or hyperæmic stage lasts from 24 to 48 hours, and an effusion that reaches any size in three or four days after that is probably as quickly formed as ever occurs. In this patient the exact time of onset of trauma was August 16th, and on the 21st, the sixth day of the illness, the physical signs showed an extensive effusion, which was confirmed by the radiogram shadow. In spite of this rapidly formed large effusion, the effect on the heart was extremely slight. There was no cyanosis, no real orthopnœa, nothing but a slight increase in the rate of breathing, with some dilatation of the alæ nasi. How far, and in what manner, a pericardial effusion under ordinary circumstances does mechanically impede the heart beat is a point upon which varying views have from time to time been expressed. Such action as it may have must be chiefly upon the thin walls of the auricles and their supply vessels, and must take the form of preventing expansion. If at any single heart beat the organ can attain a certain size, it does not seem possible for any outside squeeze to stop it from emptying itself, and if mechanical factors play any important part in creating cardiac difficulty it must be in gradually squeezing the chambers which feed the ventricles. The often-recorded anomaly that a very large effusion may cause but little obvious discomfort and the complete absence of any cardiac disturbance in this case make one wonder whether the mechanical factor of the effusion in many cases of great distress has not been exaggerated, and that the distress is really due as much, if not even more, to other effects on the heart muscle of the poison which is causing the disease.

When one considers the nervous symptoms attributed to a pericardial inflammation it is evident from their complete absence in this case that they also are no necessary adjunct of a simple acute pericarditis, but are rather due to the general toxæmia, and indicate, as does the invasion of the pericardium, a severe infection. This child seemed in no way embarrassed by the chest symptoms, the nervous system being entirely normal, so that it was difficult to look upon her as having an acute pericardial effusion at all. So much was this so that it was thought she must be one of those placid happy persons who are disturbed neither by pain nor fear. That this was not so, and that when pain or discomfort was really present she showed it in the usual way was made clear some days after the operation, when a small stitch abscess required slight attention and she made a great fuss about it. It has been said that dry pericarditis does not kill, though it frequently occurs in dying patients; is it not also possible that pericarditis has acquired its bad name largely from keeping bad company?

Sheffield.

ROYAL INSTITUTION.—At a general meeting of the members of the Royal Institution, Sir James Crichton-Browne, treasurer, announced that Dr. Arthur Keith had been appointed Fullerian professor of physiology.

THE Lord Chancellor has appointed Mr. M. J. Nolan, resident medical superintendent, Down District Asylum, as consulting Visitor in Lunacy in the place of the late Lieutenant-Colonel Graham.

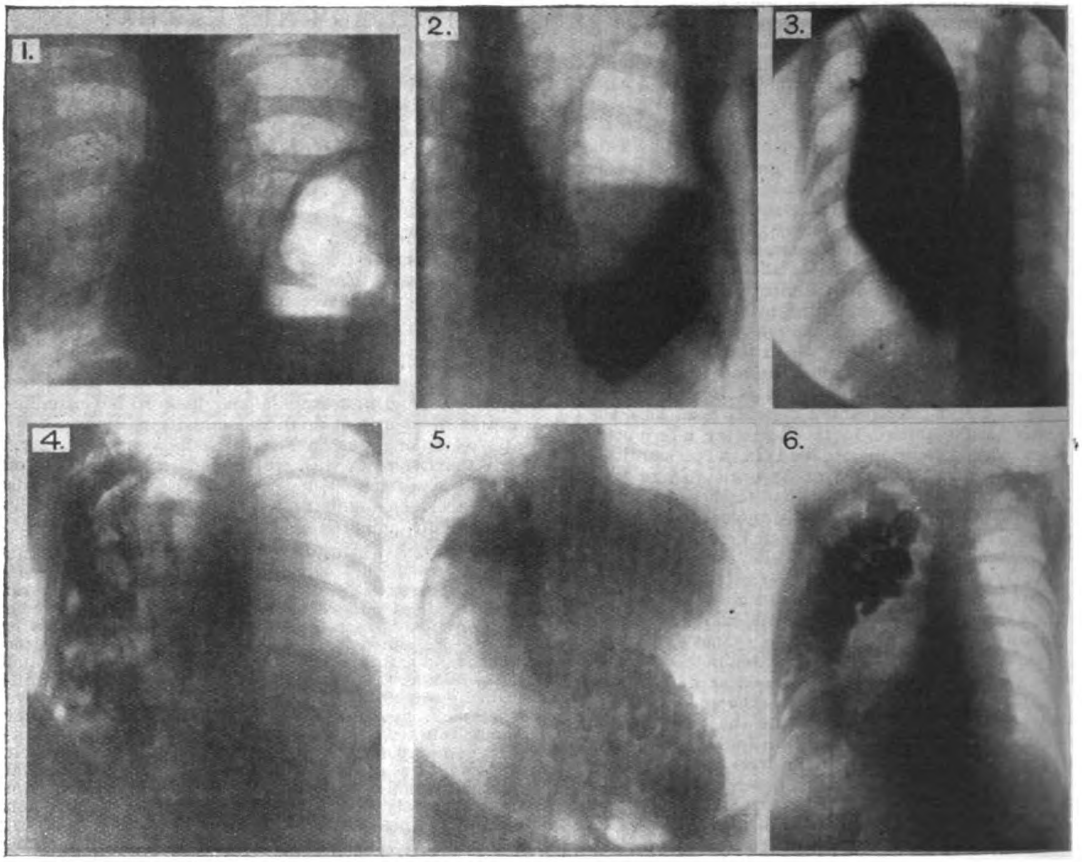
DIAPHRAGMATIC HERNIA:

WITH REPORT OF A CASE OF THE ACQUIRED CONDITION.

BY L. M. MURRAY, M.D., C.M. McGILL,
MAJOR, C.A.M.C.; KING'S CANADIAN RED CROSS HOSPITAL, BUSHEY PARK;
AND
J. D. MORGAN, B.A. CANTAB., M.D., C.M. McGILL,
MAJOR, C.A.M.C.; RADIOGRAPHER, GRANVILLE CANADIAN SPECIAL HOSPITAL, RAMSGATE.

DIAPHRAGMATIC hernia is stated to be the most common form of the internal hernia, yet it was found only three times in 13 years at the London Hospital in 699 cases of intestinal obstruction.[1] According to Scudder, a thousand cases of diaphragmatic hernia have been reported,[2] but only a comparatively small number during life. In 650 cases reviewed by Giffin, of the Mayo Clinic,[3] only 15 were reported during life. Probably a larger proportion are discovered during life now that radiographic and fluoroscopic examinations are so frequently made in abdominal conditions.

We have seen only one case reported as a war casualty,[4] although the frequency with which men in the vicinity of bursting shells are buried under a mass of earth and débris makes the accident highly probable, and should be thought of in obscure abdominal or chest conditions.



The patient, Private S. M., age 34, born in England, was admitted on April 3rd, 1917. He has been living in Canada for nearly 12 years, where he worked as an oiler in an electric light plant. He says he was always in good health before he joined the Army. His weight on enlisting was 155 lb.; it is now 122 lb. He joined the C.E.F. on May 19th, 1915, and for five months did training in Canada. He came to England Oct. 20th, 1915, and underwent another eight months' training. During the whole of these 13 months he did not have to report sick, never missed a parade, nor did he ever "drop-out" on a route march. He frequently played football, and remembers that his heart beats were always felt on the left side of the chest. He went to France on Sept. 1st, 1916, and was quite well till Oct. 24th, 1916, when he was completely buried by the caving in of a trench following the explosion of a shell. He was dug out almost immediately, but was quite unable to stand up as his back "felt as though it had been broken," and he had a severe pain which was referred to the region of the eighth and ninth dorsal vertebræ. He was then carried on a stretcher to the Courcelette dressing station, where he was given a hypodermic of morphia and sent to a casualty clearing station and then to No. —— General Hospital, Rouen; here he remained for over a month. During his stay in Rouen he was examined with the X rays (screened), but no bismuth meals given. It was evidently concluded that he had a hæmothorax (cf. Fig. 1), as his left chest was aspirated twice. On the first occasion some bloody fluid was obtained, but nothing was found on the second. He was then evacuated to England and on April 3rd, 1917, to the special clinic.

Physical examination.—A sparely-built man, colour good, but of delicate appearance, with very flabby muscles. He is able to walk five miles without distress, but any sudden exertion causes marked dyspnœa. He has no symptoms while remaining quiet.

Chest.—Left shoulder habitually carried higher than the right. Compensatory curve of the spine to the left. On straightening his shoulders the spinal curvature disappears. *Chest measurement.*—Expiration 32 inches. Inspiration 33¾ inches. Right side, at the nipple level, 16¼ inches; left side, 16⅛ inches. On inspiration the excursion of the right chest is slightly greater than the left. Tactile and vocal fremitus is much diminished on the left, below the fourth rib in front, and the angle of the scapula behind. Percussion in front, right side, resonant. Left side, resonance, to the third rib in front and midscapular region behind. Below these points a dull tympany (the type of tympany differed with various examinations).

Auscultation.—Over the right chest nothing abnormal to be heard. Left chest, breath sounds were to be heard to some extent over the whole left side, diminished, below the third rib in front, and midscapular region behind. Over this area a metallic tinkling could be heard. (This was the sign which first led us to suspect the presence of the stomach in the left chest.) Coin test present, and made out best at different points of the left chest on different examinations. On some occasions it could not be demonstrated.

Heart.—Apex beat in the fifth right interspace, 2½ inches from the right border of the sternum. A diastolic murmur was noticed at the second right costal cartilage and down the right border of the sternum. The intensity of this murmur varied with position, being more evident with standing up than on lying down. It also varied on different days, and on

1.—Patient standing. Plate anterior. Shows stomach well up into left side of thorax. Heart displaced to right. Level of diaphragm on right side is clearly shown. Free fluid level in stomach is that of ordinary meal taken a few hours before X ray examination.

2.—Patient standing. Plate anterior. Obtained a few minutes after bismuth meal had been given. Shows level of diaphragm, right side. stomach well up into left thorax; bismuth meal in lower part of the picture—i.e., in the cardiac portion of the stomach (the meal was seen to enter at this end); and the less dense shadow of ordinary meal lying above the test meal.

3.—Patient lying down. Plate posterior. The bismuth has spread out, showing the upper level of the stomach to be in region of second rib. The × indicates position of left nipple. Along the outer edge of the picture may be seen a light shadow, caused by gas-filled gut.

4.—Patient lying down. Plate posterior. Obtained some four hours p.c. At about the middle point of the picture a shadow may be seen, caused by bismuth which still remains in the portion of the stomach which passes through the opening in the diaphragm. The level of the latter is distinctly seen on the right side. A large part of the left thorax is seen to be occupied by intestines.

5.—Patient lying down. Plate posterior. Obtained about 13 hours p.c. The level of the diaphragm can be seen. The bismuth in the transverse colon is just passing through opening in the diaphragm.

6.—Patient lying down. Plate posterior. Bismuth enema. Showing large intestine in the left thoracic cavity.

some examinations was absent. Blood pressure: Systolic, 124 mm.; diastolic, 90 mm.

The spleen could not be percussed in its ordinary position.

The patient was examined by Colonel F. G. Finley, C.A.M.C., and one of us, and diaphragmatic hernia suspected. He was then given a bismuth meal and X rayed at the Canadian Hospital, Taplow, and the diagnosis of diaphragmatic hernia confirmed. Later he was sent to Ramsgate for further examination. The radiograms illustrating this report were obtained during his stay at the Granville Hospital.

A hernia may occur through the diaphragm either on its right or left side. When on the right side it usually consists of a knob of liver tissue, On the left side the contents are nearly always stomach; and then, in order of frequency, the transverse colon, the omentum, the small intestine, the spleen, the left lobe of the liver, the pancreas, and the left kidney. In addition, lung tissue may make its way downward through a deficiency in the diaphragm.[6]

Diaphragmatic herniæ are either congenital or acquired. Grasser and Thoma collected 433 cases, of which 232 were congenital and 181 acquired. Many of the congenital cases have been in stillborn babies; those who live usually go through life without symptoms, or until the onset of intestinal obstruction, when the diagnosis of the condition is made at operation or on the post-mortem table. The acquired cases are due to some trauma, such as a stab or gunshot wound,[5] or to indirect violence, causing an increase in the intra-abdominal pressure with resulting rupture of the diaphragm. The symptoms complained of in almost all of the reported cases have been dyspnœa, pain, or some indefinite gastric complaint, in some cases resembling gall-stones or ulcer of the stomach.

In the diagnosis of diaphragmatic hernia the most important evidence is to be found in: 1. Displacement of the heart to the right. This was evident to some degree in all of the cases reviewed. 2. Metallic tinkling heard high up in the chest, having relation to the peristaltic movements of the stomach, and not especially corresponding in time to the respiratory movements. 3. Tympany of some degree high up in the left chest. 4. Absence over the left chest of the dull note indicating fluid, or of the hyper-resonant note of pneumothorax.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Discussion on Surgical and Dental Treatment of Severe Facial Injuries.

A MEETING of this society was held on Dec. 3rd, Sir ST CLAIR THOMSON, the President, being in the chair, when papers were read on Surgical and Dental Treatment of Severe Facial Injuries. Major H. D. GILLIES'S paper appears in full on p. 850, and that of Captain KELSEY FRY on p. 852.

Mr. PERCIVAL P. COLE said that from the point of view of function the bony lesion was of more importance than the injury to the soft tissues, and its efficient treatment should consequently hold first place. Primary suture should not be undertaken when complicated by an associated fracture, unless the fracture could be dealt with at the same time. It was better to wait until all sepsis had disappeared and the wound was soundly healed before undertaking the necessary operative measures. The importance of cicatricial contraction was in direct proportion to its crippling effect on movement. Treatment was directed firstly to the prevention, and secondly to the rectification of such limiting effects. In the case of a cicatrising wound threatening the movements of any particular joint, it was the surgeon's endeavour to maintain the joint in that position which would most effectually conserve the movement whose limitation was threatened. In the case of opening the mouth this could be prevented by maintaining the jaws in a position of open bite. With regard to operative procedures, he said that the introduction of fresh tissue was frequently called for, and for that the use of doubly epithelialised flaps was indicated. Where there was a large demand for mucous membrane, skin made an admirable substitute, its texture was suitable, and its extent unlimited. The method of "bringing the parts together" was unsatisfactory, and should be abandoned. Pictures were then shown demonstrating the various forms of flaps used. In one case the patient was very hairy, whilst in another the flap was taken from the scalp. In these cases depilation by radiations was carried out very successfully, and Mr. Cole thought that facilities for treatment by this method should be provided in the case of any jaw centre or hospital.

Reviews and Notices of Books.

1. *Home Care of Consumptives.* By ROY L. FRENCH, M.A., former Secretary, Kentucky Tuberculosis Commission. London and New York: G. P. Putnam's Sons. 1916. Pp. 224. Price 5*s.* net.
2. *The Tuberculosis Nurse: Her Functions and Her Qualifications.* By ELLEN N. LA MOTTE. Introduction by LOUIS HAMMAN, M.D. Same Publishers as above. 1915. Pp. 392. Price $1.50.

1. THE author of this book on the home care of consumptives, who for years has been taking part in the educational and executive campaign against tuberculosis, has collected a large amount of information which he presents in the form of simple aphorisms and eminently sane advice. The illustrations of handy and cheap porches and shelters are most useful. The author insists throughout the book on the need at every stage of seeking the doctor's advice and—taking it. On the subject of marriage and parenthood, for example, he writes: "If either party to the agreement is in bad health, the relationship should not be incurred until the two people have had a full and frank discussion of the entire matter between themselves, and with a competent doctor. All three had better use pretty plain English." The book includes a useful section on foods and their preparation.

2. Miss La Motte brings to her subject the experience gained first as a nurse and later as an organiser and director of the Tuberculosis Division of the Baltimore Health Department. During many years she has, to use her own words, "walked into, and backed out of, many blind alleys ..... and acquired wisdom through the loss of infinite time, effort and money." The losses, though large, have been repaid if the yield, in this book, of shrewd observation, kindly philosophy, and common sense have their effect. Miss La Motte conducts the prospective tuberculosis nurse through a maze of detail, stipulating from the outset that the aspirant to this work must possess health, culture, and a whole string of other gifts. And they are all evidently needed, if the tuberculosis nurse is, as according to this book she must be, the guide, philosopher, and friend of the consumptive from his first sneeze to his last cough. As a matter of fact, the problems with which the nurse has to grapple in Baltimore appear to be precisely the same as those to be solved in England, whether they be the relations of nurse to doctor, to patient, to real philanthropists, or to mere busy-bodies. Consequently this book should prove as valuable on one side of the Atlantic as the other, and any nurse who has read, marked, and learned it from cover to cover should be well on her way to master the subject. We do not, however, find Miss La Motte a completely sound guide. Though she discloses no great practical knowledge of sanatoriums and their methods, she "crabs" this branch of tuberculosis work, and, speaking of the sanatorium, declares (p. 209): "We could fight quite as successfully without it—possibly better, since the money devoted to the upkeep of these very costly institutions could then be diverted to more radical purposes." Miss La Motte is hardly fair to the nurse who accepts her sweeping verdict as orthodox and unchallenged.

Congenital Word-Blindness. By JAMES HINSHELWOOD, M.A., M D. Glasg., late Surgeon to the Glasgow Eye Infirmary, &c. London: H. K. Lewis and Co. 1917. Pp. 112. Price 4*s.* net.

Dr. Hinshelwood has collected in book form various studies and observations made over a number of years in a subject to which he has devoted much attention and with which his work has helped to familiarise the practitioner. He cites in some detail various cases of congenital word-blindness that have come under his notice, in one of which there is a report of the pathological condition. The proposal is made to distinguish three groups of the affection—viz., (1) occurring more or less by itself; (2) in association with mental defect; (3) of milder degree such as is said to be common in elementary schools, being little more than a deficient aptitude. To these groups it is suggested that the terms congenital word-blindness, congenital alexia, and congenital dyslexia, respectively, should be applied. It is in a matter of this kind that the expert neurologist is unable to follow the author's contention, for these proposed terms are distinctions without a difference. There is no attempt in the book to bring the treatment of the subject into line with recent work on aphasia; agnosia, of which congenital word-blindness is but a part, is not, apparently, mentioned. For the busy practitioner, however, it serves a useful purpose in directing his notice to a not infrequent condition which may be at first rather puzzling. The chapter on treatment contains much useful and practical advice.

Collected Papers on Analytical Psychology. By C. G. JUNG, M.D., LL.D., formerly of the University of Zurich. Authorised translation by Dr. CONSTANCE E. LONG. Second edition. 1917. Pp. 492. Price 15*s.* net.

WE reviewed at length the first edition of this collection when it appeared two years ago. Two chapters are now added in which Dr. Jung develops further his ideas of introversion and extroversion. In his foreword to these new chapters the author applies his doctrines to the tragedy of world warfare. He says:—

The psychological events that accompany the present war—the incredible brutalisation of public opinion, the epidemic of mutual calumnies, the unsuspected mania for destruction, the unexampled flood of mendacity, and man's incapacity to arrest the bloody demon—are they not, one and all, better adapted than anything else, to force obtrusively the problem of the chaotic unconscious—which slumbers uneasily beneath the ordered world of consciousness—before the eyes of every thinking individual?

The psychology of warfare is undoubtedly a subject of absorbing interest which will claim the attention of the keenest minds for many years to come, but we do not know what share the rather facile views of the "psycho-analysts" will have in its solution.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

WEDNESDAY, NOV. 28TH.

THE Council resumed its sittings, Sir DONALD MACALISTER, the President, being in the chair.

Penal Cases.

The Council proceeded to consider penal cases.

The first two cases to be considered were adjourned from previous sessions, and as both practitioners could produce a good record in the intervals no penal action was taken.

In the next case the Council adjudged James George Silver Jamieson, M.D. Edin., to have been guilty of infamous conduct in a professional respect in that he had been convicted in the High Court of Justice of adultery with a patient, and directed the erasion of his name from the Medical Register.

The next case was that of Ernest Wardman-Wilbourne, L.R.C.P. Edin., L.R.C.S. Edin. Evidence having been given of a conviction at the Nottingham Assizes for an offence against a woman, his name was removed from the Register.

The Council then took the case of Reginald Nitch Smith, M.R.C.S. Eng. 1894; L.R.C.P. Lond. 1894, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you abused your position: (1) By selling to Mrs. —— at exorbitant prices, at frequent intervals, and otherwise than as a medicine in the course of your treatment of her, large quantities of a narcotic toxicant drug named heroin, and knowing that she had formed the drug habit continued so to supply her to her moral and physical detriment: (2) By selling to the said Mrs. —— the said drug at exorbitant prices and at frequent intervals for an officer and men, members of his Majesty's Forces, contrary to Regulation 40 of the Defence of the Realm Regulations, and of the Order of the Army Council, dated May 11th, 1916. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

Mr. Nitch Smith attended, and was represented by Mr. Colam, K.C., and Mr. Elsley Zeitlyn (instructed by Messrs. Smith and Hudson, solicitors).

The complainant was represented by Mr. C. F. Gill, K.C. (instructed by Messrs. Simmons and Simmons, solicitors).

Mr. GILL, in opening the case for the complainant, said that the woman being supplied with drugs by a medical man at one end of Bond-street had, under their influence, gone to the other end to steal jewellery. It was ordered by the judge at the Central Criminal Court that the action of Mr. Nitch Smith in supplying the drugs should be brought to the knowledge of the General Medical Council. The evidence showed that from January last down to her arrest in July last Mr. Nitch Smith had supplied the woman with tubes of the drug, that she had paid him by cheque, and that she frequently sent messengers for a supply.

Mr. NITCH SMITH, called on his own behalf, stated that he had practised for 18 years in New Bond-street. The patient had told him, he asserted, that she had been taking heroin when on war work in France, and that on account of the restrictions in England she could not obtain it without a medical man's certificate. She asked him to prescribe for her on two or three occasions, and then she asked him to obtain the drugs for her, which he did. She told him that she was sending some of the drug to France. He saw her 18 or 20 times, and observed nothing to suggest that the drug was acting in any way detrimentally to her system.

THURSDAY, NOV. 29TH.

Penal Cases.

The hearing of the case against Mr. Reginald Nitch Smith was resumed.

Mr. NITCH SMITH, in cross examination, maintained that he had not examined the cheques which were paid into the bank, nor taken account of them.

Re-examined by Mr. COLAM, witness said that he did not know that his attendant was supplying the drug to the woman. He had been ill for two years and had been attended by various medical men. His attendant would open any letter which came to him unless it was marked "Private" or "Personal."

Miss MARGARET HALL, attendant at Mr. Nitch Smith's rooms, in evidence said that she had acted in that capacity for 12 years, and that on many occasions she gave the patient the drug unknown to Mr. Nitch Smith.

Mr. Nitch Smith's name was erased from the Medical Register.

Two more penal cases were heard during the day, but either practitioner was removed from the Register. In one of these cases, where medical certificates had been given irregularly, the President warned the doctor of the serious nature of his offence, whilst postponing judgment till the May session of the Council.

FRIDAY, NOV. 30TH.

The Council considered the case of Bertie Cecil Eskell, registered as of 26, Zealand-road, Bristol, M.R.C.S. Eng. 1910, L.R.C.P. Lond. 1910, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you abused your position by committing adultery with Mrs. Kathleen Margaret Dobson Mercer Adam, with whom and whose husband you stood in professional relationship.

And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. John Bucknall Mercer Adam, who was represented by Mr. Holman Gregory, K.C., and Mr. Horace Rowlands (instructed by Messrs. Routh, Stacey, and Castle).

Captain Bertie Cecil Eskell, who is serving in the Royal Army Medical Corps, attended, and was also represented by Mr. R. W. Turner (instructed by Messrs. Hempsons).

Mr. HORACE ROWLANDS said that the complainant was a deputy conservator of woods and forests in Burmah. He met Captain Eskell, or as he then was Lieutenant Eskell, in the train proceeding up country from Rangoon. They found that they had attended the same school. Mr. Mercer Adam asked Lieutenant Eskell to call at his house, as he was going to the hospital at the place where Mr. Mercer Adam resided. Lieutenant Eskell had been invalided. He afterwards stayed at the complainant's house, where he met Mrs. Mercer Adam, but subseqently he went into cantonments. In June Mr. Mercer Adam broke down in health and Lieutenant Eskell ordered him to bed for a rest of a fortnight. He had also treated Mrs. Mercer Adam for troubles, and in that way counsel submitted he had acted as a medical practitioner. Mrs. Mercer Adam became pregnant. In November, 1916, Lieutenant Eskell was recalled, and counsel stated that he pressed his view that she should go to England for confinement. At Rangoon Lieutenant Eskell arranged that a medical practitioner, Lieutenant-Colonel Barry, should see the patient in consultation. He confirmed Lieutenant Eskell's opinion. Lieutenant Eskell met the lady in England, and she never went, as it had been arranged, to her husband's people. Since then counsel stated that she had lived with Lieutenant Eskell.

Mr. MERCER ADAM gave evidence. He said that when Lieutenant Eskell was living in his house a second time he treated him for a breakdown. His wife suffered from nervous attacks and Lieutenant Eskell treated her. When he asked him to treat her he (Lieutenant Eskell) suggested hypnotism. When his wife became pregnant Lieutenant Eskell advised him to send her to England.

Mr. ROWLANDS: Did you have to pay any charges to Dr. Eskell?

Mr. MERCER ADAM: I pressed him to take fees, but he refused.

In bringing this complaint in July last did you frame it to break Captain Eskell?—I considered that it was a public duty. I hoped also to save my wife from him.

Dr. E. C. ROBERTSON-FULLERTON was called as a witness by Captain Eskell. He stated that he had attended Mrs. Mercer Adam on the occasion of her confinement in this country. His opinion was that it was very undesirable that she should have been confined in India.

Captain BERTIE CECIL ESKELL also gave evidence. He stated that he had been previously in practice in Bristol, but he joined the Army in 1915. He had gone to Mr. Mercer Adam's house as a guest. He was continually there, and Mr. Mercer Adam knew it. He was not there as a medical man. A medical man staying at a house was frequently asked things. He admitted that he had formed an affection for Mrs. Mercer Adam, but the decision that she should go to England was taken on the advice of a medical man in Rangoon and not on his advice. Her husband knew that he was fond of Mrs. Mercer Adam. He admitted that misconduct had taken place, but he denied that he had occupied the position of a medical man towards Mr. and Mrs. Mercer Adam. There was never any mention of fees. He denied also that there was anything in the story of hypnotism. He admitted writing to Mr. Mercer Adam from England telling him that Mrs. Mercer Adam and he had an undying love for each other, and also that the expected child was his.

The Council adjourned.

SATURDAY, DEC. 1ST.

Penal Case.

The Council proceeded with the hearing of the case against Captain Bertie Cecil Eskell.

Mrs. MERCER ADAM, the wife of the complainant, gave evidence. She stated that Captain Eskell had been taken to her house in Burmah as an invalid. She did not want him. She always had a separate room from her husband, with

whom she did not agree. He was a very morose man and had fits in which he threw her down several times. Her husband told her to nurse Captain Eskell and he placed a mattress by the side of the Captain's bed for her to sit on.

Mr. R. W. TURNER: It is said that you were hypnotised by Captain Eskell.

Mrs. MERCER ADAM: I do not believe in hypnotism. When she saw her husband in London he told her that if he did not go back to him in half an hour he would go to the General Medical Council to break Captain Eskell and break her. She admitted that Captain Eskell was the father of her child, but she denied that he was ever her medical adviser,

Cross examined by Mr. HOLMAN GREGORY, K.C., Mrs. MERCER ADAM maintained that Captain Eskell never treated her in his capacity as a medical man.

The PRESIDENT announced that the Council having adjudged Captain Bertie Cecil Eskell to have been guilty of infamous conduct in a professional respect had directed the Registrar to erase from the Medical Register the name of Bertie Cecil Eskell.

Dental Representation.

The PRESIDENT announced that a letter had been received from the Privy Council in regard to the resolution dealing with the representation of the dental profession on the General Medical Council. It appeared to the Lord President that the proposal required legislation, for which at present there was no adequate opportunity.

Entrance Examinations.

Dr. MACKAY submitted a report by the Education Committee upon examinations in secondary schools in England. This report stated that discussion of matters connected with entrance examinations had been postponed because it was expected that important changes were contemplated by the Board of Education.

It was further stated that a new Board of Examiners was created and new system of examination tests established in September last. Should the scheme realise the expectations of those who, after much careful study, had developed and matured it, there could be no doubt that the complicated problem with which the Council, in dealing with the preliminary education of the student, had been confronted in the past, would be profoundly modified in the immediate future. Meanwhile, the Committee would advise that, at present, and until the new Examination Board had had time to complete the reorganisation with which it was charged, no further action with reference to the conditions of the examination in general knowledge be taken by the Council.

The report dealt at some length with the multiplicity of entrance examinations required by various professional bodies in England and the lack of a school-leaving certificate such as obtained in Scotland. Under the new arrangements all examinations to which the pupils of State-aided secondary schools were submitted would be under the control of a committee of experts representative in the broadest sense of purely educational interests. The "Secondary Schools Examination Council," which had been established, included representatives of all the Universities, of the managing bodies of the State-aided schools, and of the teachers. The examinations would be conducted by the Universities under the supervision of the Examination Council. There would be two examinations:—(1) The "Schools Examination," suitable for pupils of 16, and qualifying for University matriculation if passed with credit; and (2) the "Higher Schools Examination," adapted for pupils of about 18 years of age. Each school might be examined on its own syllabus; pupils would be put forward in classes rather than individually; in doubtful cases the school record would be taken into account; and the subjects included in the "pass" would be endorsed upon the certificate. Admission to the examination would be in the majority of instances by way of a definite period of instruction in a secondary school, but arrangements would be made for the inclusion of those who approached by other than the usual channels. The success of the scheme demanded the coöperation of the Universities and the professional bodies with the Board of Education, not only by the acceptance of the new certificates, but also by the refusal to recognise substitute examinations not approved by the Examination Council, which might tempt the pupil to curtail the school course. For the first time definite standards of examination for pupils at different ages were about to be established and it would be incumbent upon all who were concerned in the progress of education to assist in maintaining these. The great advantage which the scheme offered to the country by permitting the further development of school and university to take place *pari passu*, could only be realised through the avoidance of conflict of interest between the two grades of educational institutions and through the grant to the schools of complete freedom from external influences inimical to their true teaching work. It seemed to be certain that in the near future all the general entrance examinations in the country which were conducted by, or on behalf of, the Universities would be coördinated and classified, and it was to be hoped that those of the College of Preceptors, the only examining body of consequence not associated with any of the universities, would be included in the classification. If this were done, the gradual advance of the standard of the entrance examination in medicine, which had been for long an object of the General Medical Council, should now present no difficulty, as it would be possible to carry it out in strict harmony with the educational progress of the country. It was, therefore, of supreme importance that the Council should be maintained in close touch with the Board of Education and the "Secondary Schools Examination Council." It would probably be found of advantage, however, to grant to the Students' Registration Committee even a greater measure of freedom than it had exercised in the past in dealing with the educational qualifications of candidates who were above the school age.

It was at first the intention of the Education Board that a "Standing Committee" of Representatives of the Professional Bodies should be formed, and that one member of this Committee should have a place upon the "Secondary Schools Examination Council." These particular proposals were submitted to a conference of representatives of the professional bodies held in London on July 24th, and attended on behalf of the Education Committee of the General Medical Council by Dr. Norman Moore and Sir Francis Champneys. Influenced by the views expressed at the conference, the Board subsequently withdrew the proposal to grant representation upon the Examination Council to the suggested 'Standing Committee of the Professional Bodies." There remained, however, for settlement the question as to whether or not any good result was likely to arise from the formation of a committee representing interests and aims so widely divergent as those of the bodies which had been grouped together undoubtedly were. It would be seen that the delegates of the General Medical Council were of opinion that the purposes of the Council would be better served by direct communication with the educational authority than they could be were approach to be made through the suggested "Standing Committee" The Education Committee strongly endorsed this opinion.

Dr. Mackay said that this was the only report coming from the Education Committee this year on which he had any remarks to make. There was another report on the question of the compulsory inclusion of Latin in the preliminary examination in general knowledge, in which it was stated that in examinations of the junior order and open to pupils of 16 years and upwards Latin should continue to be regarded as a requirement. In this respect the committee was not recommending the Council that anything should be done at the present time. But the report as to examinations in secondary schools in England dealt with matters which were of great importance. The subject had again and again come under the notice of the Council. The work of the secondary schools had been greatly hampered in recent years by the multiplicity of examinations. The steps which the report detailed represented a prospect of advance and progress in education. In conclusion, he moved the adoption of the following recommendation:—

That as the professional bodies which demand an entrance examination are widely divergent in their aims, the Council is of opinion that they cannot be combined in a Joint Standing Committee, which might reasonably be expected to take united action. On the other hand, the Council would welcome the privilege of conference from time to time, as occasion arises, with the Education Board or the Secondary Schools Examination Committee.

Sir A. CHANCE seconded, and the recommendation was adopted without discussion.

Dr. MACKAY also moved the adoption of a recommendation to the effect:—

That the Council postpone the discussion of the subjects to be included in the junior examinations in general education until the opportunity has been afforded of observing the effects of the new examination scheme introduced by the Board of Education.

He emphasised the necessity of waiting to see what happened in regard to secondary education under the scheme of the Board of Education. The Education Committee could then report to the Council.

Dr. NORMAN MOORE seconded. He said that he had been struck by the amount of business which must be got through before the scheme of the new Board of Examiners was settled. Important as the medical entrance examinations appeared to the Council, they represented only a fragment of what had to be dealt with.

The recommendation was adopted.

Apothecaries' Hall of Ireland.

Sir FREDERICK TAYLOR submitted a report from the Examination Committee on various matters relating to the Apothecaries' Hall of Ireland. He stated that a letter had been received protesting against the employment of a deputy to attend the examinations of this licensing body. The Irish Branch Council had appointed Dr. William Boxwell as deputy to attend on behalf of the General Medical Council the examinations of the Hall for one year ending Dec. 8th, 1917. Dr. Boxwell was absent on service at the front during part of his period of office, and the Irish Branch Council in May appointed Dr. R. J. Rowlette as temporary deputy. Dr. Boxwell suggested that his report should be deferred until the termination of his year of office, and it would be presented to the Council next May. In these circumstances he moved that the Irish Branch Council should be authorised to appoint for the period of one year a deputy to be present on behalf of the General Medical Council at the professional examinations held by the Apothecaries' Hall.

Dr. N. WALKER seconded.

Dr. MAGENNIS said that he had no objection to an inspection of the examinations of the Apothecaries' Hall of Ireland provided other bodies were also inspected.

The recommendation was adopted.

Pharmacopœia Committee.

On the motion of Dr. NORMAN MOORE, the report of the Pharmacopœia Committee was adopted. It was in the following terms:—

The number of copies of the British Pharmacopœia, 1914, which were sold by the publishers between May 20th and Nov. 24th, 1917, was 1220. The number sold in the year ending Nov. 24th was 2319. The total number sold since the date of publication is thus 29,354. A third

issue of 5000 copies has been prepared; in this issue a misprint detected last year is corrected.

In pursuance of the power delegated to the committee by the Council last May, further communications on the subject of glycerine and sugar were made to the Home Secretary's Committee and other authorities. It appeared to be necessary in the national interest that immediate steps should be taken to discourage the use of these substances in pharmacy, and the committee agreed unanimously to the temporary withdrawal from the Pharmacopœia of the official directions for their use in the compounding of certain preparations. The proper notices for the alteration and amendment of the British Pharmacopœia, 1914, were accordingly published on behalf of the Council in the *Gazettes* of London, Edinburgh and Dublin, on July 27th, 1917, and are now operative. A leaflet setting forth the terms of the *Gazette* notice has been inserted in each copy of the new issue of the Pharmacopœia.

The British Medical Association has forwarded a resolution passed by its annual Representative Meeting in July, 1917, to the effect that, in the opinion of the Association, the general use of the metric system in the teaching of dispensing, prescribing, and treatment would be beneficial to the scientific interests of the medical profession. The Pharmacopœia Committee desire to express their concurrence with this opinion.

The Pharmaceutical Society of Great Britain has published a series of unofficial formulæ for certain preparations which have hitherto contained glycerine or sugar. These may usefully be adopted by prescribers in place of the formulæ that have been temporarily withdrawn. It is desirable that uniformity should, as far as possible, be preserved in the compounding of medicines which may still be ordered or dispensed under the names that were formerly official. The action of the Pharmaceutical Society in the present emergency is thus timely and useful.

Dental Education.

Mr. TOMES submitted a report from the Dental Education and Examination Committee. The committee had drawn up rules and recommendations as to the course of study in accord with the conclusions provisionally arrived at by the Council in 1916. This report was still before the Council, and it was for the Council to decide whether its consideration should be proceeded with, or, in view of the appointment of a departmental committee on the Dentists Act, should be again postponed, a course which the Dental Education Committee thought might be desirable.

In reference to this report, the University of Manchester and the University of Liverpool had reaffirmed their opinion that the minimum period for the study of mechanical dentistry should be 2000 hours at a recognised school, or 2500 hours with a registered dentist. The University of Manchester was further of opinion that private pupilage should be abolished. The University of Bristol had given a general approval to the report.

The report was adopted.

Public Health Diplomas.

Sir J. W. MOORE, in submitting the report of the Public Health Committee, stated that the committee had had before it the question of recognition of work carried out in connexion with the Army in the field in lieu of certain parts of the courses of study prescribed for the diploma in Public Health. Lieutenant-Colonel W. W. O. Beveridge, the Assistant Director for Medical Services (Sanitation) with the Expeditionary Force in France, had attended and given the committee information as to the conditions existing in the British Armies in the field which would justify temporary modifications in the rules and regulations for the diploma in Public Health. The committee had decided to suggest the adoption of certain temporary modifications in the existing rules and regulations in the case of medical officers of the Expeditionary Forces.

On the motion of Sir J. W. MOORE the following recommendation was adopted:—

Additional Note to Rule 2.—Alternative Arrangements for British Armies in the Field. That the laboratory experience at a Base Hygiene Laboratory, when and so far as approved by the General Medical Council, shall count towards the four months' laboratory course prescribed by the Council; and the laboratory experience acquired by medical officers on the staff of hospitals for infectious diseases shall count for such part of the laboratory course for the Diploma in Public Health as the A.D.M.S. (Sanitation) may recommend, and the General Medical Council on consideration may approve.

Another recommendation was adopted defining the class of officers who must be in charge of laboratories in which the course is taken under the alternative arrangement.

Medical Certificates.

Sir A. NEWSHOLME said that it was well known to some members of the Council that the national machinery of recruiting was being very seriously impeded by the unsatisfactory medical certificates received. Further publicity, he said, should be given to the remarks of the President on this subject. He should have liked if they could be distributed to every practitioner in the country, who should be informed that all certificates as to medical conditions should, whenever possible, be based on personal observation, and where that was not possible the certificate should embody a statement to that effect. This suggestion might be well communicated to the Medical Advisory Board in the Ministry of National Service with a view to consideration by them to see if any such steps could be taken.

Dr. NORMAN MOORE thought that the vast majority of the medical profession knew quite well that they ought to tell the truth. It was nothing more than that.

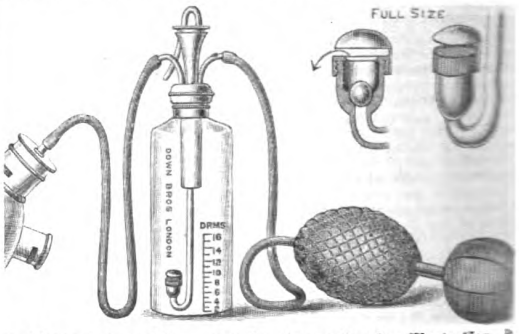
Sir A. NEWSHOLME remarked that some medical men did not appreciate the difference between the facts which came to them by personal knowledge and statements made to them. That fact needed to be brought home to a small minority.

The PRESIDENT said that the question was whether in the circumstances of the Ministry of National Service, where a large number of certificates were required from medical practitioners, it might not indicate to practitioners the nature of the certificates which alone would be accepted and be helpful for the purpose for which they were given. If the Ministry thought it desirable it would probably issue an intimation. It was suggested that the Council should communicate to the Ministry its warning notice and the passage from his speech. That would be done as a matter of communication.

This concluded the business of the session, and the Council rose, to reassemble in May.

New Inventions.

DOUBLE CINCH BINDER.



Mrs. Morison Ltd., of 47, South Molton-street, Bond-street, W., has made a double cinch binder with metal plate for a patient of mine with a ventral hernia following cholecystectomy. The hernia was the size and shape of a half cocoanut. The patient, who was a big man aged 58, with a circumference of 42 inches, can now shoot and do a good deal of farm work. Without the binder he could do practically nothing, and had many dyspeptic symptoms. The binder is well fitted at back and sides with bone stays, and buckles from alternate sides like a many-tailed bandage, so that great pressure is exerted on the hernia itself, without the binder being too tight. Moreover, the appliance is not cumbersome and is suitable for day or night wear.

Star Hill, Rochester. CLEMENT WHITE, M.D. Camb.

A MODIFICATION OF THE JUNKER INHALER.

IT is well known that accidents have at times occurred when using the Junker inhaler through the bellows having been by mistake attached to the outlet instead of the inlet tube, and the contents of the bottle so expelled. I have had made a modification of the inhaler which renders the accident impossible. As is shown in the illustration, it consists of a ball valve which is attached to the end of the inlet tube inside the bottle. It is simple, cannot get out of order, and quite does away with the danger mentioned.

Messrs. Down Bros. are the makers.

THE TREATMENT OF RHEUMATIC CONDITIONS BY PHYLACOGEN

NOTE. The clinical report quoted in this letter is published by permission. On request we shall be pleased to place any *bonâ-fide* enquirer in communication with the author.

We have never claimed that Phylacogen will cure every case of rheumatism, much less every case of so-called rheumatoid arthritis. Nevertheless, the results obtained in the treatment of arthritis by means of Phylacogen have been most encouraging, and where failures have been met with it is a question worthy of consideration whether the cases were due to rheumatic infection, or whether the arthritic changes should have been ascribed to gonorrhœal infection, syphilis, tubercular disease, or to gout.

Believing that medical men appreciate *bonâ-fide* clinical reports, we have pleasure in submitting the following, which was sent us quite spontaneously by the medical man concerned, who also gave us permission to publish his report anonymously:—

A. M., aged 26 years, states that during the winter of 1915-16 she suffered from pains in her hands and feet. In June, 1916, the joints of the little fingers of both hands became very swollen and painful. She went under medical treatment without receiving any benefit. The disease progressed until the wrist-joints and the small joints of both hands and feet became swollen and painful. In October, 1916, she consulted another medical man and received only temporary benefit. In February, 1917, she was sent to Dax and underwent a course of mud baths and internal medication. She says she was very much benefited by the course at the time, but afterwards the disease progressed and she became so ill that she had to give up her position as a governess and return home.

Towards the end of last July she consulted me and her condition at that time was as follows:—

Her general health was very poor, and when fully dressed she weighed only 112 lbs. Both wrist-joints and the small joints of both hands and feet were swollen and tender on slight pressure. She complained of pain in the right spheno-mandibular joint and in both elbows and knees, but there was no swelling. She experienced great difficulty in walking, and on account of the pain caused she "dreaded shaking hands with people." Her temperature was 99° and her pulse 84. I advised her to undergo a course of Phylacogen treatment, and she consented.

On August 7th I injected hypodermically 1 c.c. and repeated the dose in 48 hours. Keeping the interval at 48 hours, I increased the dose by ½ c.c. for two doses, and then by 1 c.c. until she had got 4 c.c. in the dose. As that caused a slight reaction I increased the interval to 72 hours and repeated the dose (4 c.c.). As the dose was now well tolerated I gradually increased it by 1 c.c. (still keeping the interval 72 hours) until she was getting the full dose of 10 c.c. The first dose of 10 c.c. caused a reaction, but the rest were well tolerated. She got in all 145 c.c. of Rheumatism Phylacogen. Her condition began to improve after she had received 12 c.c., and continued to do so during the whole course of treatment. I saw her to-day—33 days after the last dose was injected—and the improvement is maintained.

She has no pain or tenderness in any of the joints, but the swelling has not completely disappeared from her wrists or from the middle interphalangeal joint of the second finger of her right hand. She is well able to walk and the ordeal of shaking hands has no terror for her. Her general health is very good and her weight has increased by 12 lbs. Her temperature and pulse are both normal.

I would like to emphasize the absence of any great reaction; the early stage at which an improvement set in; and the marked manner in which it was maintained. I am quite pleased with the results obtained; so is the patient. (*Report dated October 30th, 1917.*)

We shall be glad to send a copy of our booklet on Phylacogen Therapy to any medical man who desires a copy.

PARKE, DAVIS & CO.
50, Beak St., Regent St., London, W.1.

Rhéantine is put up in hermetically sealed tins, containing 28 spherules.

Dosage:
Two spherules twice a day.

Rheantine is the Entero-vaccino-therapeutic method in regard to Gonococcic Treatment Messrs. Lumière and Chrevotier had since 1913 been undertaking a fresh series of experimental and clinical researches with reference to this subject. After considerable difficulties in their endeavour to find a suitable medium for the cultivation of Neisser's diplococcus, they discovered one based on the wort of beer, which perfectly answered to their requirements, and succeeded in preparing desiccated cultures, in vacuo, forming a perfectly anhydrous and stable vaccinal powder, containing about 500 millions bacilli per milligramme. This is administered in keratinised spherules. The clinical effects of Rhéantine on gonorrhœa in its various stages and in the complications of the disease are rapid, well marked, and of the most encouraging character.

From a Paper read before the Therapeutical Society of Paris (*14th June*, 1916):—

..... "Under the microscope these successive changes are demonstrated in equally definite stages; whatever may have been the duration of the disease, the characteristics of the pus become rapidly modified; after two or three days' treatment the gonococcus, first intracellular, becomes exterior; it ceases to act as a parasite on the polynuclear leucocytes and the large epithelial cells—one then finds them disseminated outside the leucocytes.

"Finally, some days later, if the administration of Rhéantine is continued, the condition undergoes still further change, the gonococci become agglutinated, arranged in a mass, and finally bacteriolysed."

These clinical and bacteriological observations constitute irrefutable proof of the efficacy of antigonococcic bacterio-therapy by the gastro-intestinal tract.

The clinical reports of various doctors or noted by ourselves, show that antigonococcic bacterio-therapeutics are capable of giving highly satisfactory results, both in acute and chronic forms of urethral gonorrhœa and also in the various infectious complications due to Neisser's bacillus.

AMBRINE

(The only Authorised Preparation of Dr. Barthe de Sandfort. Various Imitations compel us to make this statement.)

GOUT
NEURALGIA
CHILBLAINS
SCIATICA

AMBRINE instantly alleviates pain, promotes rapid healing, forms a sure Protection against Infection of the Wound.

Although the dressing with AMBRINE is occlusive and adhesive, it becomes after a short period non-adherent and can be removed without pain, hæmorrhage, or injury to the newly forming tissues. The healing takes place without leaving scars or contraction.

May be applied with camel's hair brush, but our specially designed spray greatly facilitates the application.

The BRITISH MEDICAL JOURNAL, Sept. 2nd, 1916:—

Re AMBRINE TREATMENT.

"..... The primary and quite incontestable advantages of the treatment are two: it is agreeable to the patient, because entirely painless; it is convenient to the surgeon, because easily and quickly applied. ..... It is possible that the treatment would be useful in dealing with ordinary ulcers, and in any case it is certain that the study of its application to the raw surfaces is worth pursuing. ....."

26/10/17. E——

DEAR SIRS,—I thank you for the Ambrine. I found it very effective in a chronic and very painful varicose ulceration of leg.

Please send some more Ambrine, about 5s. worth.

A. G. W.,
M.R.C.S., L.R.C.P., &c.

THE LANCET, June 10th, 1916:—

THE VALUE OF AMBRINE IN THE TREATMENT OF WOUNDS.

"Attention is being drawn to the remarkable success of the Ambrine War treatment now being used at the Hôpital St. Nicolas at Issy-les-Moulineaux for burns, frozen feet, and all wounds where the tissues have been so damaged as to exact great length of time and considerable disfigurement in their restitution by the usual means. The Minister of War in reply to the Deputy M. Mons as to why, in view of the marvellous results obtained by treating burns and frost bites with Ambrine at the Hôpital St. Nicolas, so the soldiers suffering from such wounds were not sent there, stated that this was being done as far as possible. ....."

The most efficient means and method of ensuring active **Hyperthermal-Therapy** to the practical treatment of **Varicose Ulcer, Rheumatism, Gout, Arthritis, Neuralgia,** and similar affections.

Intensive Medical Treatment.

IT is now three years since the Medical Research Committee settled down to its task of promoting investigation into the origin and treatment of disease with a view to making effective the great scheme of National Insurance, from whose funds its income is drawn. The present report[1] brings the account of work done down to the end of September, 1917, and the first glance into it confirms the obvious fact that a division of the schemes of inquiry into two sections—one of peace and one of war—can no longer be maintained except as a matter of convenience in indexing, since the investigations have become inextricably intertwined. To a nation at war any gain in the store of available medical science is a matter of vital concern, whether it immediately affects soldiers or civilians. The study of problems which emerge in war-time out of unusual and temporary conditions will have permanent value in a peaceful future. The stress of industrial work due to munition-making has stimulated a study of the laws of fatigue and of right living, while the limitation of food-supplies has forced us to gain a clearer knowledge of essential biochemical and dietetic laws.

The fact of the collection of large numbers of men under military rule has made it possible to obtain information, otherwise almost unprocurable, as in the great research into the renal efficiency of 50,000 young men leading active lives in a training camp. Medical investigation in peace-time at civil hospitals has too often been chiefly directed to the study of advanced stages of disease. War conditions have stimulated the study of the early stages in which disease can be most easily checked as well as most fruitfully studied. Prevention is more important than cure, and the rapidly organised study of irritable heart in soldiers and of the early symptoms of T.N.T. poisoning have already had results of practical importance. The employment of physiological principles in the administration of oxygen, first tested in cases of gassing and then applied to the needs of flying men at high altitudes, will of necessity react helpfully on the methods of restoration in mining accidents. The Committee states its belief that the devotion of a Government fund to research in medicine has already played a large part in fostering a growing trust in research work in other spheres. On the lowest basis the monetary gain from the Committee's work is already incalculable; each of at least half a dozen of the schemes put into practice has saved the country from expenditure which must be reckoned in multiples of the whole of the Medical Research Fund. Some readjustment of the sources of the fund, which has yielded in the current year £7000 less than was expected, is therefore abundantly justified.

The report gives telling instances of the value of assembling a large number of similar cases, whether medical or surgical, for the purpose of collective study, and another good example can be found in the papers, which we print in the present issue, by Major H. D. GILLIES and Captain W. KELSEY FRY. They are the first of a series from the Queen's Hospital for Facial Injuries at Sidcup and well illustrate intensive treatment. At this hospital the rapid evolution of the successful remedy of apparently hopeless facial injury has largely been the result of friendly rivalry between a number of active intelligences brought to bear upon collected material of an unusual character. Such an intensive culture of scientific method under the stimulus of collective interest and criticism is here seen to produce results which could hardly have been attained by a generation of sporadic individual effort. It is worth while to try to draw the right conclusions from this success, because it cannot lie merely in the grouping together of similar cases in institutions. No point was brought out to more effect in the recent discussion on sanatorium treatment at the Medical Society of London than the disastrous result which may attend the grouping together of cases of chronic disease, unless the necessary stimulus towards recovery is provided. Dr. HENRY ELLIS'S remark in that debate that institutional treatment of the tuberculous might fairly be judged by the presence or absence of what he termed "sanatorium disease" evidently commended itself to many of his hearers. Whatever the administrative advantages gained, the assembly of patients suffering from similar ailments is, at least from the medical point of view, a questionable undertaking unless a continued evolution of the methods of recovery is present as a constant stimulus to staff and inmates alike. Our record of asylum practice is none too encouraging in this respect, and the detailed rather than the concentrated treatment of neurasthenic cases, which has received much influential support has its foundation on this fact. Intensive treatment does not necessarily imply institutional treatment, which presents its own particular difficulties and dangers.

The Personation of Medical Practitioners.

SIR DONALD MACALISTER, in the presidential address at the winter session of the General Medical Council, which has just been concluded, called serious attention to the fact that the present shortage of medical men was inducing unqualified individuals to personate registered medical practitioners; and we have received from a correspondent a suggestion that on registration all medical men should have their finger-prints officially taken.

for he believes that personation of medical men by impostors is common. Our correspondent's letter was provoked by the recent case of the man SIDDONS. It will be recalled that SIDDONS, who was committed for trial at Liverpool Assizes early in the autumn, for personation of a medical man among other things, escaped justice by committing suicide a few days before his case would have been heard. Conviction upon some at least of the charges against him was certain, and the Defence of the Realm Act would have been found to have added penalties to those incurred by persons who are detected in signing certificates and otherwise posing as duly qualified medical practitioners without being such. SIDDONS, or VIRTUE, as his name in comical fact was, if not uniformly successful in a criminal career, was an ingenious and pertinacious rascal. At some time of his life he obtained a sort of training in the direction of veterinary medicine, but he found that to pretend to be a medical man, and to personate some individual not likely to be confronted with him, offered a better opportunity of earning a living. His most striking performance consisted in the personation, a few years ago, of Mr. R. H. BARBER, a medical man who had been drowned abroad and whose name had not been removed from the Register. In the character of R. H. BARBER, SIDDONS practised medicine for five years in various places without being detected, but belated suspicions being aroused the charge of personation was easily established. The expiry of a sentence for this offence of nine months' imprisonment in the second division left him at liberty to resume his courses, and the war, which commenced soon after his release, afforded him a good opportunity. The bogus practitioner was not, however, satisfied with drawing illegal emolument for services which he could not render: he endeavoured to enrich himself by underclassing the recruits whom he examined, and awoke thus the official vigilance which had been sadly at fault when he secured his responsible position.

The whole story came as somewhat of a shock to the public, as we have had recent occasion to learn; so that it may be well to point out that no large number of impostors of the SIDDONS type can exist at any one time in the kingdom, and that very few of these escape ultimate detection. There may well, however, be such persons, and Sir DONALD MACALISTER'S warning proves that their existence is likely; nor need we wonder, when we read in the police reports of their ultimate detection and punishment, how they managed to succeed for a brief period. Such men usually live in crowded centres where they can practise chiefly among the poor and ignorant, without associating themselves in any way with the medical life of the locality. If thrown accidentally into communication with any of those with whom professional comradeship has been assumed, they can decline from motives of taste to talk "shop," or can ask to be reticent concerning the confidences of a patient. A rank impostor would assuredly betray himself if he made any close medical acquaintances, but by steering clear of all association with medical men a surface familiarity with practice will cover depths of ignorant pretence. Reference to the Medical Register or Medical Directory if doubt arises does not settle the matter of qualification in the case when the deceiver is also an impersonator, who can only be detected by some inconsistency of dates or localities with apparent age or appointments. It may not be desirable that medical men should play the part of detectives and be unduly curious as to their colleagues' antecedents, but at the same time where the credit of their profession and the safety of the public are both concerned, their expert knowledge is rightly exercised in setting on foot inquiry to be carried out by others if a legitimate reason occurs for suspecting fraud. The Medical Register is now most carefully kept, but no amount of zeal on the part of the Registrar will entirely prevent fraud while many of the medical profession neglect to notify the bureau of changes of address. Government departments and public authorities should above all exercise extraordinary care at the present moment, when a shortage of qualified medical men is accompanied by wholesale, if temporary, changes in their address. Apart from the evidence of the Medical Register and the *Medical* Directory, personal identification should be required if the slightest doubt arises. Very few men or women would be desirable candidates for any medical post who could not produce proof of their identity from some other member of the medical profession.

To return to the suggestion that medical men should have their finger-prints taken on registration, to be kept in an official record, it may be pointed out that, apart from the objection to maintaining a record only used as yet for criminals, the proceeding would be an act of unnecessary precaution when applied to medical men. In trying a recent case at the Westminster police-court Mr. ROOTH declined at first to receive evidence as to previous convictions of a prisoner based upon finger-print records, which were the only proofs of those convictions. Although it was stated that the prisoner, when confronted with the records of his previous misdeeds, had admitted them, the magistrate insisted that there should be personal identification by witnesses who saw the prisoner on the previous occasions referred to. On a later day, however, he passed sentence without waiting for such additional evidence, after explaining that he had gone into the whole matter personally at Scotland Yard and had satisfied himself that the risk of error was very small, and that a strong *prima facie* case was made out when finger-prints and photographs of the person accused combined to establish identity. None the less, he was right in his intent to look for further evidence in such cases. Finger-prints afford a most valuable, and now indispensable, means of identifying and indexing persons who pass through the hands of the police. But a certain possibility of error on the part of those handling such records exists, even if a similarity of prints cannot conceivably lead to injustice. Personal identification alone is not a safeguard against a miscarriage of justice. The BECK case, for example, showed clearly how personal identification

at any rate by unpractised and perhaps prejudiced witnesses, may err. In practice, also, a judge or magistrate would give weight to a prisoner's strenuous and consistent denial of crimes with which finger-prints alone had connected him, and to any apparently honest alibi. In such a case personal identification can always be invoked, but, as a rule, prisoners are too conscious of their previous delinquencies and of the strength of the evidence of finger-prints to dispute the matter. We do not think that the provision of means of identifying registered medical men by their finger-prints is in the least called for, but we do feel that, where any doubt could arise as to a man's right to the name which he is using, the furnishing of personal identification should be a necessary prelude to any appointment.

Annotations.

"Ne quid nimis."

EPSOM COLLEGE.

THE financial position at the present moment is bearing hardly on all classes; those who are more fortunate in worldly position have many calls upon their purse, and, on the whole, are responding well; the other section of the community are bearing the strain of the increased prices bravely; but the net result is that all charities are appealing for the poorer to persons who themselves are growing poor. This condition of things applies to the medical foundation of Epsom College, for while annual subscriptions have been lost on account of the war and because so many medical men are engaged away from their homes on military duty, on the other side, in addition to the normal calls for assistance, there are an increasing number of dependents of victims of the war who need help. Already the governors have elected as a Foundation scholar the son of a medical officer in the Royal Navy who was killed in action on board H.M.S. *Good Hope*, and there are on the list of candidates the son of a medical officer in the Royal Army Medical Corps who was lost in the *Royal Edward* when she was torpedoed in August, 1916, and the son of a medical officer who was killed last April. From Sir Henry Morris's letter, which appears in another column of this issue, as well as from the statement in our advertising pages, it will be seen that although much effective assistance has already been given the applicants far exceed the number of foundation pensions and scholarships that are available. We have pleaded the cause of Epsom College for so many years that it should not now be necessary to insist upon the duty of every medical man to subscribe to an institution which in the chances and changes of life may be called upon to minister to the needs of many. We hope that every member of the profession, who is able, will either send a donation to, or become a governor of, this necessary and worthy institution.

THE X RAY DIAGNOSIS OF GALL-STONES.

THE difficulties and uncertainty which surround the evidence from X rays in relation to the detection of gall-stones have long been familiar. The character of the stones, their varied translucency, and the vagueness of the shadows they may present have been factors responsible for the undoubted tendency to ignore the possibilities of roentgenology for their detection. However, a strong case has been made for the practical value of these methods by Dr. J. T. Case, of Battle Creek, Michigan, whose experience is almost unrivalled. He states his views and the evidence on which he bases them in a paper, entitled "The Value of the X Ray Examination in Cholelithiasis," in the *Annals of Surgery* for July. He divides gall-stones into three groups: 1. Composed of pure cholesterin; these are quite invisible to X rays. 2. Stones containing a relatively large quantity of lime salts; these are easy to detect. 3. The largest class, made up of stones in which the amount of lime is relatively low. It is the detection of these cases which determines success or failure of the method. A chemical analysis was made for Dr. Case of the lime content of a number of gall-stones. Where the X rays were negative and yet gall-stones were found at operation, the percentage of calcium oxide in relation to the total weight of the stone was 0·30. Among the positive cases—i.e., in the instances where the X ray evidence of the presence of stone was confirmed, but where shadows were most difficult to detect and were seen only upon very careful oblique illumination of the roentgenogram—the lowest proportion of calcium oxide was 0·425 per cent. These examples, doubtless, fall under Class 3. Now Dr. Case found that, in a series of 1000 consecutive bismuth-meal examinations, there were 40 instances of gall-stones; in Cole's series of 500 similar cases, quoted by him, gall-stones were found in 20 cases—the same percentage in each series. The figure 4 per cent. represents roughly the number of positive findings; for autopsy statistics from 19 American and European authors the average frequency of gall-stones is given as 5·9 in 18,892 autopsies. Hesse summarises 17,402 autopsies done in ten years in Petrograd, and finds gall-stones in less than 3 per cent. Dr. Case accepts, however, a generous 10 per cent. of probable gall-stones in his gastro-intestinal and genito-urinary cases combined, and thus finds that positive X ray examination has been gained in roughly 50 per cent. of cases. Similarly, in a series of 5000 consecutive patients examined for suspected disease of the gastro-intestinal tract, lumbar spine, or right kidney (instances in which the region of the gall-bladder would be automatically included) positive findings were made in 4·5 per cent. of the cases. Again, accepting 10 per cent. as possible gall-stones, 45 per cent. of these were demonstrated by X rays. These are, of course, only estimated figures. Accordingly Dr. Case took a series of 300 consecutive abdominal cases operated upon, in which the gall-bladder was examined at the time of operation as well as by X rays beforehand. Gall-stones were found at operation in 41 cases, and of these, 20 had been reported "positive" by X rays; here again, roughly, half of the gall-stones can be detected in this way. X rays are claimed as of value also in gall-bladder disease, in many cases showing right upper quadrant adhesions with fixation and even sometimes the thickened gall-bladder. Finally, the author says:—

> We can therefore conclude that it is definitely possible to show gall-stones in approximately 50 per cent. of the positive cases and to show a gall-bladder lesion in 85 per cent. of cases of gall-bladder disease. ..... Gall-stones are demonstrable with much greater frequency than has until lately been conceded. The frequency with which stones may be shown is so great that I believe the time has arrived when the X ray examination should be required in every suspected case.

DIAPHRAGMATIC HERNIA AS A SEQUELA OF WAR INJURIES.

DIAPHRAGMATIC hernia is not a very uncommon condition, but it has in the past generally been overlooked. With the increasing employment of the fluorescent screen in all obscure abdominal cases the diagnosis is likely to be made more frequently during life. Few cases have as yet been reported as the result of gunshot wounds, possibly because the hernia in case of injury to the diaphragm often does not develop until some time after the injury. Such a case is very completely described by Major L. M. Murray and Major J. D. Morgan in our present issue. The man was completely buried by a shell explosion, and when dug out was unable to stand on account of pain referred to the region of the eighth and ninth dorsal vertebræ. On aspiration of his left chest some blood-stained fluid was obtained, but the hernia was not suspected until after his evacuation to the Canadian special hospital, when metallic tinkling was audible over the left chest. A bismuth meal and X ray examination confirmed the presence of the hernia, the relations of which are admirably shown in the series of X ray prints. Another case has recently been reported by Gustav Ranft,[1] the man dying 16 months after a gunshot wound of the lung. The case is thus described:—

> Within ten weeks after the injury the man seemed to have recovered so completely as to be returned to duty, and, indeed, he served in the field two or three times. In the intervals, however, he was admitted to hospital for gastric catarrh, which seemed of an ordinary kind, and for pain in coughing and sneezing. Eventually bronchitis and pleurisy supervened, from which he died. At the necropsy the lowest third of the left pleural cavity was found to be almost completely filled by bowel tightly distended with liquid fæcal matter. It was the transverse colon, and had penetrated into its unusual situation in the thoracic cavity by means of an opening in the diaphragm large enough to admit two fingers. Dense adhesions bound the intestine to the diaphragm, and round the opening were old scars.

The author concludes that in wounds of the lower thoracic region the possibility of a traumatic diaphragmatic hernia should always be kept in mind. If on further investigation the suspicion is found to be confirmed, the patient should not be pronounced militarily fit, lest, as in this case, serious or even fatal disease of the respiratory organs ensues.

ACUTE ANGIO-NEUROTIC ŒDEMA DUE TO A DOSE OF KHARSIVAN.

OUR knowledge of the possible toxic effects of salvarsan and its substitutes has been acquired only gradually. Why they occur in a few cases and are absent in the majority has not been satisfactorily explained. The suggestions made by Ehrlich and his followers that they are due to administration in unsuitable cases, in which grave organic disease of the nervous or circulatory system is present, or that they are due to errors of technique, have been negatived. There remain only the somewhat unsatisfactory explanations of idiosyncrasy to account for toxic effects following a first dose, and of anaphylaxis to account for the more frequent occurrence of toxic effects after a second dose. In the *Journal of the Royal Naval Medical Service* for October, Surgeon Roderick J. G. Parnell and Temporary Surgeon W. C. P. White have reported a case in which a dose of kharsivan gave rise to a previously undescribed toxic complication—acute angio-neurotic œdema—though an almost identical case had been observed by Staff-Surgeon Paul Fildes.

A stoker, aged 45 years, was admitted to Haslar for primary syphilis. The heart, lungs, urine, and alimentary and nervous systems were normal. On Oct. 29th he was given 0·5 gramme of kharsivan. On the same evening his temperature rose to 99·6° F., and he developed a well-marked Herxheimer reaction. In the morning his temperature was normal and all traces of reaction had disappeared. On Dec. 8th the dose of kharsivan was repeated. During the injection he was somewhat restless, but he made no complaint, and it was presumed that he was merely nervous. Twenty minutes later he became collapsed with an almost imperceptible pulse, face swollen and somewhat cyanosed, and lips and eyelids œdematous. He was unable to speak and very restless. Soon he began to secrete saliva with great freedom, so that paroxysms of distressing cough, due to the saliva passing down his throat, occurred. After about five minutes he could speak in a whisper and complained of pain in the throat, over the heart, and in the pit of the stomach. An intramuscular injection of ether and a hypodermic injection of adrenalin were given. The foot of the bed was raised and a pint of saline solution was injected into the rectum. He gradually improved. He was turned on his side to aid the outflow of saliva from the mouth and the œdema was obviously less 1½ hours after the onset. The buccal mucous membrane was very œdematous. After 3½ hours the salivation and cough were less, but he complained of slight headache and was inclined to sleep.

Staff-Surgeon Fildes's case was as follows:—

> A powerfully built officer who had a large chancre containing *Spirochæta pallida* and a positive Wassermann reaction as the only manifestations of syphilis was given 0·6 gramme of salvarsan. A severe reaction, against which he had been warned in view of his clinical condition and the absence of treatment, followed. He shivered during the night, vomiting and diarrhœa occurred, and next morning a profuse macular syphilitic rash had appeared. On the following morning he returned to duty. Ten days later the dose was repeated without ill-effect. A month later it was repeated again, all signs of syphilis being absent. Within five minutes he had a metallic taste in the mouth. A few minutes later the taste was worse and he complained of pain going down his throat. He was found sitting on the bed with bloodshot eyes and suffused face. The lips, face, and eyelids became swollen, and watery fluid poured from, or was spat from, the mouth. The heart was extremely irregular, weak, and rapid. The voice became progressively weaker until he was unable to speak. He then gradually improved. After about three hours it was possible to observe that the whole buccal cavity and tongue were still markedly œdematous.

Surgeon Parnell and Surgeon White ask why the drug selected the area of the fifth cranial nerve for distribution of the lesions. Laryngeal œdema did not occur. If it had the cases would probably have been fatal.

PELLAGRA IN THE WEST INDIES.

IN 1913 Dr. L. W. Sambon,[1] under instructions of the Colonial Office, visited the British West Indies to investigate a diease, reported to be pellagra, prevalent in some of the islands, and to study the conditions under which the malady was appearing, so that appropriate measures for its prevention might be formulated. Dr. Sambon has prepared a preliminary and a further report, the first dated 1915, and the second 1917. These have now been issued with a prefatory note by the Colonial Office, stating that it was considered undesirable to defer publication, though the report was still incomplete. Dr. Sambon expresses the definite opinion that, though only recently recognised in that region, the disease is an ancient one in the West Indies; he adds that after carefully examining a considerable number of cases, in all stages of the malady, the disease he saw was genuine pellagra, differing in no way from the pellagra seen in Europe and the United States. He

[1] Deutsche medizinische Wochenschrift, 1917, No. 22.

[1] West Indies, Reports on Pellagra in the West Indies, by Dr. Louis W. Sambon M.D. Naples. London: Published by His Majesty's Stationery Office. 1917. Pp. 62. Price 6*d*.

found it associated frequently with other complaints, of which he gives an enumeration, and this association of disorders sometimes rendered the diagnosis difficult. "Pellagra," according to Dr. Sambon, "like leprosy, syphilis, and tertian fever, which have an equally world-wide distribution, is identically the same disease wherever found, whether in Europe, Asia, Africa, America, or Oceania." Discussing the etiology of pellagra and reviewing a mass of evidence, Dr. Sambon concludes that food plays no part in the production of the disease and that maize, sound or unsound, has nothing to do with the causation. The opinion held by some experts in this country and America that pellagra should be classed as a "deficiency" disease due to an ill-balanced and monotonous diet does not receive in the present report the consideration that one might have expected, nor are the human experiments of Goldberger and others in support of it mentioned.[1] Dr. Sambon originated the hypothesis that pellagra is an insect-borne infectious disease, but in his present reports he does not adduce much in support of this view. Probably the evidence in reference to conflicting theories as to the causation of pellagra will appear in an extended report which is foreshadowed.

AN APPEARANCE OF COLOUR SPECTRA TO THE AGED.

AN interesting note on this subject appears in a recent number of *Nature* from that veteran ophthalmologist, Mr. R. Brudenell Carter, founded on personal experience. He finds that he sees rainbow colours surrounding any small light viewed at a distance sufficiently great not to produce contraction of the pupil, and since the condition of his own eyes is, with optical correction, absolutely normal, he attributes the phenomenon to some senile change in the crystalline lens of each eye which does not affect the acuity of vision. The appearance of such spectra is not quite confined to the aged, for a later correspondent in *Nature* recalls an observation of Tyndall's in which an artist was for a time troubled with coloured rings. We think that Mr. Carter is correct in his lenticular interpretation of the phenomenon, while the change may be none other than those non-progressive opacities seen in the periphery of the lenses of many old people, which the late Mr. W. H. H. Jessop used to call "arcus senilis lentis." We do not know, but we make the suggestion to Mr. Carter, who will appreciate it at its worth.

THE report of the Advisory Committee of the Central Control Board (Liquor Traffic), under the chairmanship of Lord D'Abernon, is nearly completed. It deals with the action of alcohol on the human organism, and will be published in the near future as a book and at a price that will make it accessible to the general public. Lord D'Abernon's committee consists of Sir George Newman, Professor A. R. Cushny, F.R.S., Dr. H. H. Dale, F.R.S., Captain M. Greenwood, Major W. McDougall, F.R.S., Major F. W. Mott, F.R.S., Professor C. S. Sherrington, F.R.S., and Dr. W. C. Sullivan, and we may fairly expect from such a body of experts an unbiassed and authoritative statement.

Dr. A. J. Rice-Oxley has been re-elected chairman of the Public Health Committee of the council of the Royal borough of Kensington.

OUTBREAKS OF PLAGUE ON S.S. *SARDINIA* AND *MATIANA*, 1917.

BY W. M. WILLOUGHBY, M.D., B.C., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH, PORT OF LONDON.

The Outbreak on the s.s. Sardinia.

THE s.s. *Sardinia*, from Melbourne, *via* Bombay and the Mediterranean, arrived at Gravesend on May 2nd with a crew of 45 Europeans and 129 natives of India and 32 passengers. Five cases of plague had occurred during the voyage. Two natives died on the way up the Channel and were buried at sea, a third died before removal, and two more cases were discovered in the examination of the ship on arrival at Gravesend. The two cases and the corpse were removed to the isolation hospital of the Port Sanitary Authority and the ship was detained at Gravesend. On the following day, May 3rd, a lascar was found to have fever without other symptoms and was removed to hospital; he died of plague on May 8th. A seventh case was taken ill on board on May 6th and died of plague on the 9th. Six of the seven cases were in natives of India and one in a British storekeeper.

The ship's movements were as follows: Left Sydney, Feb. 23rd; Melbourne, Feb. 26th; was at Bombay March 19th to 22nd; thence *via* Aden, Suez, Port Said, and Malta to Marseilles, where a stay from April 13th to 16th was made for discharge of cargo. After further discharge of cargo at Gibraltar on April 22nd the ship arrived in the Channel on April 29th and at Gravesend on May 2nd.

Tabulation of Cases.

	Rating.	Berthing in forecastle.	Date taken ill.	Result.
1	Lascar.	Starboard.	April 27th.	Died Apr. 30th.
2	Coal-trimmer.	Lower.	,, 27th.	,, May 1st.
3	,,	,,	May 1st.	Recovered.
4	Fireman.	Port.	,, 1st.	Died May 2nd.
5	Storekeeper.	Alleyway.	April 28th.	Recovered.
6	Lascar.	Starboard.	May 3 d.	Died May 8th.
7	,,	,,	,, 6th.	,, ,, 9th.

Cases 1, 2, and 4 presented large cervical buboes, Cases 5 and 7 presented femoral buboes, and Case 3 presented an inguinal bubo. Case 6 was a septicæmic one without local lymphatic incidence; from beginning to end the only sign was fever. Films made from the viscera of Cases 4, 6, and 7 at the hospital gave abundant bipolar bacilli. Pus from Case 3 was found by the pathologist to the Local Government Board to be infective on animal experiment.

The British storekeeper, Case 5, gave a straightforward history of onset, being awakened in a shivering fit and finding tenderness in the region of the femoral glands in the early morning of April 28th. None of the cases were pneumonic in type at any stage of their history.

All the cases occurred in the fore part of the ship. The starboard top-gallant forecastle is devoted to deck crew and the port to the firemen and coal-trimmers. Approached from the port forecastle is a 'tween deck quarters appropriated to the coal-trimmers. Cases 1, 6, and 7 were in lascars who berthed close together in the starboard forecastle. Cases 2 and 3, in coal-trimmers occupying the 'tween deck quarters, and Case 4, in a fireman occupying the port forecastle, berthed next the stairway leading to the 'tween decks. The British storekeeper lived in a cabin opening into the starboard forecastle alleyway. It is noteworthy that the native food was kept in a storeroom in the forepeak, approached by a trap and ladder in the floor of the starboard forecastle; also that the natives' galley was situated amidships at the forecastle. The native food-store was quite shut off from direct communication with the holds, being situated ahead of the collision bulkheads.

Rats.

The cargo from Australia consisted largely of wheat, flour, skins, and dried fruits; that from Bombay of pears, lentils, and Acajou nuts: the holds would therefore form an attractive nidus for rats. At Bombay traps were procured on account of the number of rats which had been seen since leaving Australian ports. At Marseilles fumigation of the foreholds with sulphur dioxide took place, the cargo

being *in situ;* the fumigation was carried out by means of the Clayton apparatus. I am informed that it is usual to fumigate holds containing more than 500 tons of cargo destined for Marseilles from an infected port such as Bombay. Three dead rats were thrown out from the carpenter's store-room adjoining the food store and situated in the forepeak soon after the ship left Marseilles. The significance of the dead rats was not noticed at the time; the mortality was ascribed to the Marseilles fumigation, although the rats were found in front of the collision bulkhead where fumes could not have reached them.

The ship left Marseilles on April 16th and the first human case occurred on April 27th. It was said that a sick rat had been seen by some member of the crew soon after leaving Port Said; this history was obtained subsequent to the rousing of considerable interest among the crew in the matter of sick rats. I am, however, inclined to believe that a sick rat, or rats, were seen before Marseilles was reached. The British storekeeper, one of the first cases, issued the native stores, for which purpose he went periodically down into the storeroom, often only in slippered feet. In a former experience of plague in the port the issue of native stores was the duty of the *kasab*, and he alone of the crew was attacked by the disease; he had thrown dead rats out of the storeroom; his bubo was femoral also.

It is probable that infected rats found their way on board at Bombay with the food cargo taken there, and that the infection was more or less confined to the holds until arrival at Marseilles; and that here rats, some of which were infected, gained access to the forecastles and food store, infecting the rat inhabitants already in the forecastle quarters, and themselves taking up their habitation there, where the galleys and the food store formed an ample attraction. The fumigation of the foreholds at Marseilles gives rise to the suspicion that rats may have been even driven to the living quarters; it is a difficult matter to effectively fumigate the holds in the presence of cargo. The hatches were lifted after fumigation at Marseilles and again at Gibraltar. In addition to the possibility thus afforded of infection taking place along the deck, the following structural detail is worthy of notice. The chain lockers on the *Sardinia* are connected to the bilges by a scupper; this is a good exit for rats from the holds in case they are disturbed there. The chain lockers communicated with the lower forecastle by a trap-hatch, which was opened at Bougie and again at Gibraltar to stow chain. The chain locker would form a refuge for rats in case of an incomplete or ineffective fumigation. Two of the cases occurred in the lower forecastle. These facts may have a joint significance. Again, the native food store is ventilated to the extreme forecastle-head by a goose neck; the chain pipes and this goose neck form a path of no difficulty to a rat, from chain locker to food-store. The partial fumigation is thus a possible determining factor in the human outbreak. Theoretically, holds should not be fumigated where infection is suspected without simultaneous fumigation of at least that human accommodation to which access from the holds may be gained by rats.

Preventive Measures.

The measures taken with a view to prevention of spread of plague on board and ashore were as follows:—

The cases were removed to hospital and the whole of the crew and contents of the infected quarters removed for bathing and steam disinfection respectively. While the men were bathing at the disinfecting station their clothes were passed through the Washington Lyon apparatus and their quarters on board fumigated by burning sulphur candles, one pound to the 1000 cubic feet therein. This implied the simultaneous fumigation of the forepeak. The time of exposure to sulphur dioxide was over 15 hours. These measures were calculated to make the living quarters temporarily safe for habitation with respect to rats and fleas.

The passengers were landed forthwith on arrival; their names and addresses were forwarded to the several sanitary authorities at their destinations in accordance with the system of "surveillance" which has superseded quarantine in this country. The crew remained on board under daily observation; if a member of the white crew were permitted to go off the ship for a short period "surveillance" was assured.

Cargo was completely discharged into barges while the ship lay on quarantine grounds and before the fumigation for finally ridding the ship of rats was made. This implied observation of each package passed overside to see that no rat escaped therewith; the mooring ropes of the barges were guarded against escape of rats by way of them. The grain cargo was shot out of sacks overside, flour sacks were scrutinised to prevent possible transfer of a contained rat. Bundles of skins would form a likely nidus; these were watched both on loading and discharge of the barges; a dead rat was found in one of these bundles. As further precaution much of the cargo was stored for 14 days or longer and a watch set on the rat population of the neighbourhood of storage. Goods for transmission to America may require certification either of freedom from infection or of disinfection. Goods stored thus were certified.

The ship-workers were clad in overalls tied in at the ankles and wrists against possible attacks by fleas; all workers were placed under "surveillance" in the way described for passengers. Everybody concerned with the ship was alive to the danger from rats and to the circumspection with which they should be treated whether alive or dead.

On complete discharge the ship was filled by means of the Clayton apparatus with 3 per cent. sulphur dioxide gas.

A single illustration shows the necessity of simultaneous fumigation of crew accommodation and holds.

The cabin situated opposite the insulated meat store in the port alleyway amidships was filled with fumes from No. 4 hold on fumigation of this hold; the store was similarly filled. The connexions between the hold and these rooms were rat runs. Under fumigation of the holds alone rats could be driven into these places and thence into the whole of the adjoining quarters; this would be the more likely to occur if, owing to the presence of cargo or otherwise, the fumigation were rendered inefficient or diffusion slow. Forty-one dead rats were found on search after the fumigation.

The ship arrived late on May 2nd. Case 7 occurred on May 6th and the precautionary fumigation of quarters was made on May 3rd. I am of opinion that nobody was infected after these precautionary measures. Three cases from the starboard forecastle bunked in close proximity to one another suggests the possible direct infection of Cases 6 and 7 through fleas from Case 1 without the intervention of the rat. The point is of interest, as there is the bare possibility of reinfection of the forecastle before the ship was discharged of cargo and finally fumigated. I think, however, this had not occurred.

The measures taken were completely satisfactory: in the result no human or rat infection gained the shore. The ship left the district on May 17th, outward bound.

The Outbreak on the s.s. Matiana.

The s.s. *Matiana* from Bombay *via* the Cape arrived at Gravesend on August 13th last, and nine cases of plague were reported to have occurred since the ship left Delagoa Bay; six of the native crew had died and three were removed convalescent to Denton Hospital. On August 14th a fourth native of India was taken ill and died of plague on August 16th in Denton Hospital.

The ship left Bombay, the port of lading, on June 9th and was at Delagoa Bay from June 26th to July 8th. Cargo was discharged there. As a preliminary to discharge the foreholds Nos. 1 and 2 were "fumigated" by means of cylinders of gas thrown into them.

The list of crew attacked is as follows:—

—	Rating.	Age.	Reported ill.	Bubo.	Result.
1	Saloon boy.	30	July 16.	Axillary and supra-clavicular.	Recovered.
2	Lascar.	19	,, 16.	None.	Died July [illegible]
3	Punkah boy.	22	,, 17.	,,	,, ,, [illegible]
4	Lascar.	20	,, 17.	Right femoral.	,, ,, [illegible]
5	,,	27	,, 17.	Right submaxillary.	Recovered.
6	Coal-trimmer.	20	,, 22.	Left groin and neck.	Died July [illegible]
7	Lascar.	19	,, 24.	None.	,, Aug. [illegible]
8	,,	22	,, 25.	,,	Recovered.
9	Serang.	29	,, 28.	,,	Died Aug. [illegible]
10	Lascar.	—	Aug. 14.	Right axillary.	,,

It is probable that Case 8 who only presented severe bronchitis while in hospital, had not been plague-infected at the time of his illness. Pneumococci were plentiful in his sputum and *B. tuberculosis* and *B. pestis* absent. It will be seen that 17 days separate the first group of 9 cases from the tenth case. All the cases except No. 6 occurred amongst the

part of the crew berthed in the forecastle. The firemen and coal-trimmers were berthed in the 'tween decks amidships on the port side. All the native crew was Mahommedan, and the native galley was situated in the starboard alleyway to the forecastle. The firemen therefore would have dealings with the forecastle and its occupants from time to time, and this association may account for the infection of a single fireman, although, on the other hand, the mortality of rats and its distribution show that the ship from stem to stern was plague-infected in the holds.

The port forecastle, devoted to saloon boys, was only separated from the sailors' quarters in the starboard forecastle by open battening. Six of the 10 cases occurred in the sailors' quarters and only 2 among the saloon boys. The case in the serang, who was lodged in the starboard alleyway in quarters bounded on the one hand by the forecastle and on the other by the native galley, brings the proportion to 7 sailors and 2 saloon boys. The point is a small one, but the list to starboard in case incidence is paralleled by the location of the native food in preparation and storage.

Comparative immunity among the saloon boys may be due to the fact that their meals are partly taken in the saloon quarters and much of their time spent there, away from the forecastle.

Rats and Fumigation.

After 3 deaths, on July 22nd the forecastle was thoroughly cleared of all contents and the crew camped on deck. Ten dead rats were found during this clearance in the forecastle and one in the native food store, which is situated ahead of the collision bulkhead and is without ingress to rats or human being save by a trap in the floor of the starboard forecastle. One of the ten dead rats was found lodged in the bundle of clothing which had belonged to a lascar dead of plague.

Under the direction of Dr. W. L. Mayer, the ship's surgeon, the forecastle was washed down with disinfectant and fumigated, first by means of formalin, then by sulphur burned in liberal quantity. The native clothing and bedding were steamed in a tub. These measures were evidently effective as regards the infection in the forecastle which caused and resulted from the first nine cases.

The occurrence of the tenth case on the day after arrival in the Thames showed, however, that infection was still present on the ship up to the time of arrival. Smears taken after death from this case gave abundant bipolar bacilli, confirming the diagnosis of the epidemic, which, however, was not in doubt in view of the abundant clinical and historical evidences.

The cargo consisted largely of oil seed and myrobalans, attractive to rats and shipped at Bombay.

During the homeward voyage 42 rats had been trapped, in addition to those found dead in the forecastle. In the discharge of the cargo in Gravesend Reach 77 dead rats, mostly of the *Mus rattus* (black rat) denomination, were found. *Mus decumanus*, however, existed on board; a specimen was trapped and examined for plague at the hospital with negative results.

A rat plague infection of the holds must, on the facts, be assumed to have occurred at Bombay. It was a month after leaving Bombay and a week after leaving Delagoa Bay that the first human case occurred.

At Delagoa Bay a fumigation of the forehold was attempted in the presence of cargo, and the distribution of the rat mortality in the holds as disclosed on the discharge of cargo at Gravesend is as follows:—

Hold No. 1, 5; No. 2, 9; No. 3, 34; No. 4, 29.

Why this paucity of dead rats in Nos. 1 and 2, the "fumigated" holds, as compared with Nos. 3 and 4, the unfumigated?

The suspicion is very strong that in this fumigation rats were evicted from holds Nos. 1 and 2 rather than killed, and that, as suggested in the case of the *Sardinia*, these took up their quarters in the forecastle, which afforded cover and food.

The details of the measures taken at Gravesend are the same as in the case of the *Sardinia*, save that the barges were only permitted to lie alongside during actual work, and no debagging was considered necessary except from sacks which on scrutiny were found holed so as to permit entrance, and thus transfer, of a rat.

No human infection took place on board after the preliminary fumigation at Gravesend, and I believe no infection reached the shore except in the removals to the disinfecting station and hospital.

Remarks.

Plague-infected ships are rare arrivals in the Thames. It is significant that two outbreaks in quick succession should have appeared, and both in ships in which partial fumigation had been carried out. If, as I assume, there is a direct connexion between these partial fumigations and the human outbreaks, two points of great importance arise.

First, the ship's structure and possible paths of communication for rats must be closely investigated in connexion with any partial fumigation of a ship and the necessary protection against invasion of living quarters by rats arranged for. No fumigation of holds should be attempted without simultaneous fumigation of living quarters to which a possible path of escape for rats exists.

Secondly, had the human cases not occurred, would the rat infection existing on the ships have been disclosed at the moment for most effective action? Rat infections do pursue their course in undisturbed holds both with and without eventual recognition of the fact of their occurrence.

In practice the present safeguard against the landing of infected rats which may exist on ships from infected ports is the power of port sanitary authorities to put questions and make examinations concerning rat mortality and sick rats. The time for putting the questions is necessarily protracted over the whole period from the ship's arrival to completion of discharge of cargo, and in the absence of repetition of the questions from day to day a discovery of importance may not be disclosed at the proper time for effective action, if at all.

As an additional safeguard it seems desirable that the duty of ascertaining as far as possible the state of the ship with regard to rats both on the voyage and during discharge of cargo, and of immediate notification to the port sanitary authorities of sick or dead rats found, be imposed on owners and officers or other persons in charge of ships as part of the Orders of the Local Government Board relating to plague.

Greenwich.

THE PROPOSED MIDWIVES BILL FOR IRELAND.

A BILL to secure the better training of midwives in Ireland and to regulate their practice was introduced in the House of Commons on Nov. 12th by Mr. Duke, the Chief Secretary for Ireland, and ordered to be printed. It is briefly known as the Midwives (Ireland) Bill, 1917, contains 29 clauses, and closely follows the lines of the Midwives (Scotland) Act of 1915, which was itself modelled on the English Act of 1902 with certain alterations and additions resulting from the experience gained in the administration of the English Act during a period of more than 12 years.

It will be of help to our readers to note the provisions which appear in the Irish Bill but not in the English Act nor (unless so specified) in the Scottish Act.

Clause 2 (1) (b) and (c), and (2).—A claim for the Irish certificate may be made within two years from the commencement of the Irish Act by a woman who holds a certificate in midwifery granted after training and examination by any lying-in hospital recognised as a training school for midwives by the Local Government Board, or by a woman who has been a permanent midwife of a workhouse or a dispensary district in Ireland.

Clause 3 (1), (2), and (3).—The Central Midwives Board for Ireland is to consist of thirteen persons, of whom eight are to be registered medical practitioners, four are to be appointed by the Local Government Board (two of whom are to represent the County and County Borough Councils), and one is to be a certified midwife appointed by the Lord President of the Council. As in the Scottish Act, the members of the Board are to be paid in respect of their attendance reasonable expenses on a scale approved by the Privy Council.

Clause 6 (1) (a) and (b).—The Board is authorised to suspend a midwife from practice in lieu of removing her name from the roll, and the local supervising authority is authorised to suspend from practice, until the case has been decided, a midwife against whom a prosecution has been taken for a contravention of any of the provisions of the Bill. (In the Scottish Act.)

Clause 6 (2).—The local supervising authority is authorised in certain cases to pay reasonable compensation for loss of practice to a midwife who has been suspended. (In the Scottish Act.)

Clause 7 (1), (2), and (3).—The Board is authorised to pay all or any part of the expenses incurred by a midwife who may be required to appear before them in her own defence. All forms and books which midwives are required to fill up or use are to be supplied free of charge by the local supervising authority or the Board. (In the Scottish Act.)

Clause 8.—Where the name of a midwife has been removed from the roll the Board may prohibit her from attending women in childbirth in any other capacity. (In the Scottish Act.)

Clause 9.—Where a midwife's name has been removed from the roll she must within 14 days after notification thereof surrender her certificate to the Board under a penalty not exceeding £5. (In the Scottish Act.)

Clause 10.—A notice of the removal from the roll of the name of a midwife is to be given to the Local Government Board as well as to the local supervising authority.

Clause 11.—Provision is made for admission to the roll on reciprocal terms of a woman trained and certified after examination as a midwife in any other part of H.M. Dominions where there is an Act or Ordinance for the certification and registration of midwives under a public authority. (In the Scottish Act.)

Clause 12.—A woman whose name has been removed from the roll may appeal within three months to the High Court or to the Local Government Board. In England the appeal is to the High Court only, and in Scotland to the Court of Session only. It is hardly conceivable that the Local Government Board should be given coördinate jurisdiction with the High Court either in England or in Scotland, where the powers of the Judicature and of the Executive Government are not alternative.

Clause 13.—The Board's accounts are to be audited by an auditor appointed by the Local Government Board. In the English Act the Board appoints its own auditor, and in the Scottish Act the auditor is appointed by the Secretary for Scotland. Precepts for payment of the deficiency may be issued to the local supervising authorities in proportion to the rateable value of their districts. In England the precepts are levied in proportion to the number of midwives who have given notice during the year of intention to practise within the various areas, and in Scotland the precepts are to be in proportion to the populations of the various districts.

Clause 17.—For the purpose of exercising the powers of supervision over midwives, powers of entry at reasonable times and on certain conditions are given to the local supervising authority in respect of premises believed to be a lying-in home conducted for profit. (In the Scottish Act.)

Clause 21.—Power is given to local supervising authorities to contribute towards the training of midwives within or without their respective areas. (In the Scottish Act.)

Clause 22.—Provision is made for the payment by the local supervising authority of fees on a scale to be fixed by the Local Government Board to medical practitioners called in to the assistance of a midwife under certain conditions. (In the Scottish Act.)

Clause 23.—County councils may appoint a registered medical practitioner with qualifications to be approved by the Local Government Board to be their medical officer for the purposes of the Bill, and in a county borough the medical superintendent officer of health shall be the medical officer for the purposes of the Bill.

Clause 29.—This clause contains a curious misprint showing that the bulk of the Bill has been copied verbatim from the Scottish Act, and provides that the Act may be cited as the Midwives (Ireland) Act, 1915—an obvious error for 1918.

Comparing the Irish Bill with the Scottish Act, from which it is taken, it will be observed that the chief difference consists in the much larger powers given to the Local Government Board in Ireland. This is no doubt due to local conditions, which are in many respects quite different from those obtaining in England or Scotland. The name "Local Government Board" does not appear in the English Act at all, and in the Scottish Act it is found only in Sections 22 and 23 dealing respectively with the scale of fees to be prescribed for the payment of medical assistance in cases of emergency, and the annual report of the medical officer of every local supervising authority which is to be sent to the Local Government Board. Clause 12 contains a principle open to grave objection, and its amendment, limiting jurisdiction to the High Court only, is suggested as a wiser course. There is no clause in the Irish Bill or Scottish Act authorising a county council to delegate its powers to any district council within its area, as in the English Act. The Bill provides that the rules regulating the practice of midwives shall be communicated to the General Medical Council for its observations before they are officially approved by the Privy Council. It is proposed that the measure shall come into operation on Jan. 1st, 1918.

MANUFACTURE OF DRUGS IN INDIA.—Writing on the conditions in the Madras Medical Stores, perhaps the largest of its kind in India, the *Madras Mail* remarks that the mistaken economy in medical matters which led to the breakdown in Mesopotamia is exemplified in the case of such stores. At present, in addition to meeting the ordinary requirements of the Presidency, the superintendent has to supply drugs to the numerous special hospitals and convalescent depôts in the country. Owing to the embargo on freight, he has been obliged also to break new ground in the direction of manufacturing in the country drugs which until lately used to be imported. Careful inquiry has been undertaken into the possibilities of growing in India various medicinal plants, and search is being instituted for mineral substances used in the manufacture of drugs. Madras hopes to be able to make its own disinfectants, more especially of the phenol group, and also starch from rice. The possibilities of making glycerine are also being investigated.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of THE LANCET.

SIR,—I would again ask you to allow me to make an earnest appeal to your readers for contributions to the Royal Medical Foundation of Epsom College. This Foundation provides an education of the highest class, together with maintenance, clothing, and pocket money, for 50 necessitous sons of medical men, and gives pensions of £30 each to 50 aged members, or widows of members of the medical profession in reduced circumstances. In order to maintain the full numbers of beneficiaries a sum of about £4500 must be obtained by annual contributions.

I appeal to all medical men as well as to members of their families who do not already contribute regularly, to assist the Council at this particularly difficult time by becoming annual subscribers. In the case of those who do subscribe, I earnestly request them to increase if possible their regular contribution during the period of the war, and subsequently for two or three years at least. An increased number of applications is sure to be received as a consequence of the war. Already the governors have elected as a Foundation Scholar the son of a medical officer who was killed in action on board H.M.S. *Good Hope;* and there are at this time on the list of candidates the son of a medical man who was lost in the *Royal Edward*, when she was torpedoed in August, 1916, and the son of another medical officer who was killed whilst in command of a battery in France last April.

I am, Sir, yours faithfully,

HENRY MORRIS.
Honorary Treasurer of Epsom College and its Royal Medical Foundation.

8, Cavendish-square, London, W., Nov. 27th, 1917.

THE THEORY OF "BACK PRESSURE" AS A CONSEQUENCE AND AS A CAUSE OF HEART FAILURE.

To the Editor of THE LANCET.

SIR,—There come periods when newer acquisitions are apt to engross the attention to the prejudice of older possessions, and among the latter I would instance the doctrine of "back pressure" in its relation to heart failure; this of late has been called in question for reasons which, to me, appear to be more than inconclusive.

Heart failure declares itself when under the normal conditions of life an effective circulation ceases to be maintained.

The object of this letter is to consider one particular form of heart failure—namely, that caused by valvular disease; to take note of the phenomena of back pressure as these are developed by the central impediment; to find in these phenomena both an expression of heart failure and a measure of its degree; and, finally, to show how back pressure reacts upon the heart muscle itself, impairing its functional activity, and thus augmenting the cardiac incompetence. In this last respect it is claimed that back pressure, itself a *consequence* of heart failure, becomes secondarily an actual *cause* of heart failure.

I. *Back pressure as a consequence of heart failure from valvular disease.*—Let us take as an example of this disease the button-hole mitral. The result of the thickening and fusion of the valve segments is that a resistance is interposed in the course of the circulation of the blood through the chambers of the heart. This resistance works by the development of a reactive pressure which, by preventing the forward delivery of the blood, leads to the accumulation of blood behind the obstruction. The effect of this accumulated (residual) blood is first felt by the heart itself as a distending force, but in the course of things as it outsteps certain reserve powers of the heart, termed compensatory, it is projected backwards into the great systemic veins and is felt ultimately in the farthest venules and in the capillaries themselves. For brevity's sake I have not followed the effects of the button-hole mitral through the lesser circulation; it is unnecessary. This is back pressure; its cause

is the central impediment; its working is as retrograde as the flight of the Parthian arrow: is it not well named?

To see the above-named effects as *pressure* effects, it will be simplest to observe the sequence of events which arises when a vein is tied or otherwise obstructed. What happens? The movement of the blood in the veins is stayed at the obstruction and that portion of the *vis a tergo*, which until that moment had been expending itself, first, in developing the liquid momentum of the flowing blood, secondly, in overcoming the surface resistance of the vessel walls, now, as the blood comes to a standstill, appears as a distending force and the vein swells immediately behind the block. This process repeats itself, as, successively, the oncoming blood is held up, until the venules and capillaries are reached. If the distending force is able to push past the obstruction, well and good; if it cannot the rise of pressure and distension go on increasing until a maximum[1] is reached and the *vis a tergo* is counterbalanced by the stretch of the tissues. Under the raised pressure the capillaries, in particular, ooze in excess of the drainage capacity of the lymphatics, and the part becomes more or less water-logged. In this area of engorgement, of stasis, of high blood pressure and of exudation (œdema), the functions of the part are brought more or less to a standstill and disintegration preponderates, completing the picture of relative death occasioned by the block.[2] Fortunately for the part there are few if any closed vascular circuits, in the sense of being quite shut off from neighbouring areas; in the vast majority there are collateral channels which interconnect more or less freely. These anastomotic channels constitute a reserve mechanism which safeguards the vitality of the blocked area by relieving the congestion therein and gradually re-establishing the circulation. The operation beginning at the periphery proceeds centrally, and we may note that it is the raised blood pressure, itself a secondary effect of the venous obstruction, which now comes to the rescue and opens up the collateral vessels.[3] Incidentally, we may note that this raised blood pressure is not always so intelligently directed, for whilst it always tends to open up the collateral paths it also tends at the same time to force the blockade, and sometimes with success, as in the case of thrombosis. But the local relief thus secured is at the imminent peril of the whole, since the potentiality for evil of the embolus is of far greater moment than the local congestion. But this is by the way. After such manner does the venous obstruction work, and it matters not how small or how large is the vein involved the process is always the same—viz., by the backward projection of a raised intravenous pressure.

To come back now to the obstruction placed centrally in the heart, again the *modus operandi* is exactly the same, and under its influence the right heart and the whole systemic venous system tend to become congested and stagnant. As a preliminary to this (the block being at the mitral orifice) there will be the congestion of the veins, capillaries, and arteries of the pulmonary circulation, in particular of the hinder and lower parts of this circuit. In one respect, however, an important difference obtains between the effects of the block in the vein and the block at the heart, for whereas in the former, even though the obstruction be in the inferior or superior cava, anastomosis always gives local relief, more or less, in the latter, anastomosis cannot serve, since the whole venous system is involved. There is one exception to this statement: it holds when the cardiac obstruction arises in fœtal life, before the completion of the interventricular and interauricular septa; in that case a kind of anastomosis is secured by the prevention of the completion of the septa and by the maintenance of the patency of certain fœtal channels. By these means life may be made possible though upon a lower level.

I am unable to quote figures as to the exact values of the intravenous pressures in heart failure from valvular disease. In health physiologists put the pressure in the large veins at the root of the neck at 0 to minus 0·8 mm. Hg[4]; in disease, in the absence of precise records, we may, I think, assume safely that the pressure is always raised whenever there is fullness of the veins at the root of the neck—e.g., a distended external jugular; for if there were the smallest negative pressure at the outflow of the external jugular, or even a zero pressure there, the blood could not be dammed back so as to distend the external jugular and lift the skin over the vein; there must be a positive pressure in the vein to do this. The distended external jugular will therefore always indicate a plus intrathoracic venous pressure unless there be evidence of local compression of the vein.

II. *Back pressure as a cause of heart failure.*—In the ordinary way we do not speak of back pressure as the cause of heart failure, but as its expression or consequence and in the main this is its most important aspect; now, however, we are to consider how it may be a definite cause of cardiac incompetence. The first roots of the systemic venous system are constituted by the coronary sinus and the coronary veins which open into it, and when back pressure develops as a result of cardiac obstruction these veins will, in a sense, be the first to feel the effects of back pressure, the first to suffer from the general venous stasis. But we have seen that vascular stasis involves a lowering of the vitality of the congested tissues, this can hardly be called in question, consequently the heart muscle, impaired in its nutrition, must suffer in its driving-power, and therewith another form of heart failure adds itself to the pre-existing failure from *mechanical obstruction*. We have here a good example of the vicious circle, so-called.

It is strange that a modern school of cardiologists would restrict the essential cause of heart failure to a functional impairment of the heart muscle; this is about as reasonable as to say that bowel failure can only result from functional impairment of the intestinal musculature, whereas we know that a mechanical obstruction—e.g., a strangulation—of the intestine or an impacted fæcal mass may defy the most healthy and vigorous peristalsis, threatening death unless the obstruction be removed. Here the failure is as mechanical as is its relief. True, a paralysis of the bowel may bring about a failure as complete and as fatal in the absence of all mechanical obstruction, but this is no argument against the other variety of bowel failure.

In the foregoing the obstructing valve has received chief attention, but the leaking valve leads to exactly the same results, for the regurgitation develops a reactive pressure as effective as the simple passive resistance of a narrowed orifice in holding up the circulation.

In conclusion, it must be said that however much modern advances in cardiology may have in store for us, they have not so enriched us up to the present that we can afford to forgo those older standards which have stood the test of time. Amongst these standards we must place those back-pressure effects with which we are all familiar; and we must insist that to belittle their significance is not in accordance with clinical experience, that *argumentum ad ægrotantem*, which, in dealing with the sick man, his griefs, their cure or their relief, must ever speak the final word.

I am, Sir, yours faithfully,

HARRINGTON SAINSBURY.

Wimpole-street, W., Nov. 21st, 1917.

[1] According to Halliburton, the complete closure of the veins leading from a capillary area may quadruple the capillary pressure (Physiology, edition 1917, p. 273); this pressure, since we are now dealing with a problem in hydrostatics, should represent the venous pressure also.

[2] Dr. Charles Bolton (Observations on the Pathology of Cardiac Dropsy, Oliver Sharpey Lectures, 1917) attributes the chief part of the œdema to the disintegration of the capillary wall.

[3] With the re-establishment of the circulation the raised blood pressure, of course, falls. Cf. the experiments of C. Bolton, loc. cit.

THE VALUE AND LIMITATIONS OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 24th two important matters were dealt with.

(1) In Professor Sims Woodhead's and Mr. Varrier-Jones's article a statement was made, to which you referred in your leading article, on which I should like some further evidence.

"It is stated on very good authority that the results of sanatorium treatment vary according to the class of person treated, and that amongst the well-to-do the results of treatment are three times as good as are those obtained with the working men."

I should be very glad if the facts or statistics could be published on which this statement was founded, as it certainly does not accord with my general impression and is absolutely contradicted by the Australian Commission's figures, published in a recent number of your journal, where it was shown that in Australia 222 per 100.000 persons of independent means died from tubercle in 1911, as against only

200 per 100,000 among miners, the highest death-rate among the working-class, and only 36 per 100,000 amongst dependents. A statement so far-reaching and important as that the rich recover easier demands very accurate proof.

(2) Concerning Dr. Louis Cobbett's letter *re* Success and Failure in the Treatment of Tuberculosis. While quite agreeing with him that the time has not yet arrived for the general use of prophylactic injection, and believing, as he does, that it must rest entirely on its own foundations, there are, in addition to the points he has suggested, two further points which at the present time give one a hope that it may be a definite remedial procedure. The first is, so far as I have been able to observe, that lupus tissue which has been attacked and has recovered seems to be immune from further invasion, the invasion always occurring at the free edge of the disease. Secondly, the application of tuberculin to the infected conjunctiva in repeated doses, at least in my hands, has produced such a condition of resistance that ulceration, or breaking down, though frequent previously, does not recur. Freedom from relapse has been demonstrated practically in all cases tested, most of them for a period of over two years.

I am, Sir, yours faithfully,

Middlesbrough, Nov. 27th, 1917. HENRY A. ELLIS.

HYSTERICAL DEAFNESS IN SOLDIERS.

To the Editor of THE LANCET.

SIR,—The questions raised in the interesting paper by Major A. F. Hurst and Captain E. A. Peters in THE LANCET of Oct. 6th are of the greatest importance. It is certain that many applications for compensation will be made by soldiers who claim that their hearing has been injured or destroyed by the explosion of mines, shells, or hand grenades, or by prolonged gun-fire. There may be great difficulty in adjusting these claims as the hearing power of recruits has not been systematically examined. Thousands of men suffering from deafness—with or without otorrhœa—have been admitted to the Army. Sohier Bryant[1] gives some startling figures regarding the number of "ear" cases in the various zones of the French Army.

Major Hurst and Captain Peters state that organic disease or injury of the ear of sufficient intensity to produce severe cochlear deafness is invariably accompanied by loss of vestibular reaction. They apparently apply this law not only to cases of shell deafness but also to those of neuro-labyrinthitis due to epidemic cerebro-spinal meningitis. The logical conclusion is that if, in testing a case of shell deafness, or neuro-labyrinthitis we find that the vestibular reactions to the rotation and caloric tests are normal, we may conclude that the deafness is either hysterical or malingered. If this is really true it immensely simplifies the work of otologists in examining such cases. I, however, agree with Dr. P. McBride in thinking that we must hesitate a little before accepting this delightfully simple test as a reliable one for the purpose of excluding organic injury or disease of the sound-perceiving apparatus. It is a pity that Major Hurst and Captain Peters do not give an account of any cases of "explosion" injury of the ear in which they have found loss of the vestibular reaction.

We must confess that as yet we do not know the exact pathology of "shell" or "explosion" deafness. We can, of course, observe ruptures of the tympanic membrane when these are present, but we know that such ruptures, even when associated with hæmorrhage into the middle ear spaces, will not account for the marked or absolute deafness met with in cases of severe shell deafness. There are three other changes which may account for the condition: (1) Rupture of, or hæmorrhage into, the membranous labyrinth; (2) hæmorrhage into, or rupture of, the cochlear nerve or some of its fibres in the internal auditory meatus; and (3) degenerative neuritis of the nerve structures of the cochlear apparatus—i.e., Corti's organ, spiral ganglion cells, &c. In a paper on this subject at present appearing in the *Journal of Laryngology* (in conjunction with Captain John Fraser, R.A.M.C.) I have shown that, out of four cases of explosion injury of the ear microscopically examined, (1) rupture of the delicate neuro-epithelial sacs and tubes of the membranous labyrinth was not found in any case. (2) Hæmorrhage into the cochlear nerve at the fundus of the internal meatus was present in three out of four cases. Such a lesion is quite capable of producing deafness. In one case there was a large plug of wax in the external meatus which seems to have protected the structures of the middle and inner ear from injury.) (3) An early stage of degenerative neuritis was probably present in one case in which the injury was due to the explosion of a hand grenade close to a soldier. (Microscopic examination of a case of shell deafness which dies from other causes some months or years after the onset of the deafness would give more reliable results as to the presence or absence of degenerative necrosis. From these rather meagre observations we may at least state that there is some pathological basis for explosion deafness. I must, however, admit that, as all the cases examined by Captain Fraser and myself were admitted to the casualty clearing station in a state of profound shock and died shortly after admission, no vestibular or cochlear tests were carried out.

I can, however, bring forward the case of a congenital deaf-mute in which microscopical examination of both inner ears showed that Corti's organ in all coils was so malformed that hearing was almost abolished, while the vestibular structures were normal. The caloric reaction was tested on both sides some days before the death of the patient and a normal response was obtained. Another case which throws some light on this subject was that of a patient who had suffered from chronic middle-ear suppuration and absolute deafness on one side for many years before death. (The vestibular reactions unfortunately were not tested as the case came under observation before such examinations became a routine part of otological work.) Microscopic examination of the labyrinth showed complete obliteration of the whole cochlea by new bone formation and atrophy of the cochlear nerve. The structures of the vestibule and semicircular canals along with the vestibular nerve, on the other hand, were comparatively well preserved. These two cases show that the function of the cochlea may be entirely lost while the vestibular apparatus is normal (Case 1) or shows but slight alteration on microscopic examination (Case 2). Those who have had experience in carrying out the functional tests of the cochlear and vestibular apparatus in cases of otosclerosis will have come across instances in which the patient is extremely deaf (mixed middle and inner ear deafness), whereas the vestibular apparatus responds normally to the rotation and caloric tests (Fraser and Walker[2]). These observations show that the cochlear apparatus is not always normal when the vestibular apparatus responds to the caloric test.

Professor A. A. Gray has shown[3] that in the evolution in the animal kingdom the vestibular apparatus appeared long before the cochlear apparatus. The former is present and fully developed in the lower fishes, whereas the cochlea only begins to appear in the reptiles and amphibians and reaches its full development in the higher mammals. It is usually admitted that organs such as the vestibular apparatus which appear earlier in the scale of evolution have greater resisting powers or greater powers of recovery than those which, like the cochlear apparatus, are developed at a considerably later period. I know that your correspondent Dr. Dan McKenzie does not agree with this view.

Let us, however, look at the matter from the point of view of ordinary anatomy and physiology. There are two movable areas in the rigid bony capsule which surrounds the labyrinth. These areas—the oval and round windows—are situated in the party wall which separates the middle from the inner ear. The former—the oval window—communicates with the perilymph space of the vestibule just at the point where the scala tympani of the cochlea begins. The latter—the round window—lies at the other end of the perilymph space of the cochlea. As the labyrinth capsule is rigid and as fluid is incompressible we must conclude that movements of the perilymph, produced by vibration of the stapes in the oval window, can only occur in that area which lies between the two movable windows. It would seem therefore that a "blow" to the ear caused by a sudden great movement of the atmosphere following an explosion is transmitted to the oval window and can only affect the column of fluid in the cochlea. This helps to explain the greater vulnerability of the cochlear apparatus. We must, however, admit that a very violent explosion close to a soldier can shatter the skull including the temporal bone. The "rigidity" of the labyrinth capsule is therefore only a relative term.

[2] Journal of Laryngology, November, 1914, p. 519.

[3] Otosclerosis, Lewis and Co., London, 1917, p. 56.

do not deny that there are many cases of hysterical ifness following shell explosion or prolonged gun-fire. jor Hurst and Captain Peters have given us two very eresting instances of this condition. What I do deny is t we can accept without further consideration the law l down by these writers that the presence of normal tibular reactions excludes the possibility of serious injury he cochlear apparatus.

Ve must conclude that, while it is very difficult for Major rst and Captain Peters to prove their contention, it is by means easy to show that they are wrong.

I am, Sir, yours faithfully,

linburgh, Nov. 26th, 1917. J. S. FRASER.

ROPHYLAXIS IN VENEREAL DISEASE.

To the Editor of THE LANCET.

IR,—I am not sure that I understand Sir Bryan Donkin's er in your issue of Nov. 24th. I did not imply, at any I did not mean to imply, that calomel cream, if used in icient strength (30 per cent.), is not effective as a pro-lactic in syphilis. As a fact it is efficacious even hours ir actual inoculation. Since it is a germicide, it is bably effective also against gonorrhœa if it be used before cocci have entered the urethra. I merely insisted that antiseptic, quickly used, is equally efficacious. Sir an Donkin questions whether permanganate of potash ild prevent syphilis if abrasions were present on the is. I can only answer that when permanganate was used a single case of venereal disease occurred during many ths among some thousands of men dwelling in a com-nity where venereal disease was rife. I presume, even n abrasions are present micro-organisms do not instantly below the surface. I am not alone in my experience, am I the first to use this method. Since writing to LANCET I have learned that some years ago a surgeon, had care of a large body of men in one of our endencies, provided his charges with pill-boxes con-ing permanganate in crystals and with instructions o use. Thereafter he also saw not a single fresh case of ereal disease. I do not think either of us is entitled redit, except in so far as we had the courage of our victions. It is obviously the correct procedure, when so ited and accessible a part of the body as the penis has n exposed to infection, to disinfect at once—to practise inary surgical cleanliness. Again, it is obviously right n the moral standpoint to prevent disease (i.e., poison-), especially when the innocent suffer with the guilty.

he point I especially wished to make is this: Calomel am is not the only nor, as far as I am able to judge, the st universally useful means of prophylaxis. It is seldom and. I do not know to what extent it has prevented ase among controlled bodies of men. I am sure it has next to no prophylactic influence among the general lic. Men do not seek medical advice before going into ger, nor afterwards till too late. On the other hand, manganate or some other antiseptic is found in half the es of England. Its use is universally understood. If ere known that simple sponging with a solution of it vented venereal disease the knowledge would quickly ead. We might hope, if not entirely to abolish venereal ase, to make it as rare as typhus or typhoid, and by the e means—suitable sanitation. Legislation, so hard to ain and so ineffective when obtained, would be un-essary. I am, Sir, yours faithfully,

uthsea, Nov. 25th, 1917. G. ARCHDALL REID.

CCESS AND FAILURE IN THE TREAT-MENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

IR,—I am much indebted to Dr. Louis Cobbett for his ellent and pertinent criticism of my views as to the hods of dealing with the tuberculosis problem, in your e of Nov. 24th. Before taking his criticisms in order I ild like him clearly to understand that I desire to use and every means both to prevent tubercle bacilli obtain-access to the human and the bovine body, and, if they btain access, to make sure that the seed falls on stony and, and that the tissues of the body are able to destroy Dr. Cobbett accuses me of ignoring the nature of the case. If I do not understand the nature of the case I ought to, having recently read his excellent book on the problem. He instances the special methods of dealing with diseases such as malaria and bubonic plague, where the infection is transmitted by animals which can be killed whether they are infected or not. He is quite right. The animals which transmit tuberculosis and pneumonic plague cannot be exterminated, but I do not ignore that any more than he does. These instances only emphasise the special difficulty of preventing individuals, human and bovine, from being infected.

In his book Dr. Cobbett insists on the importance of the size of the dose of bacilli, which gain access to the host, in producing disease, and also on the virulence of the infection. In all animal experiments the test of immunity is the capacity to withstand the inoculation of large doses of bacilli which are virulent for the particular animal—viz., of bovine bacilli for the ox and the rabbit and of both human and bovine for the guinea-pig. Now, I am quite aware that complete immunity has never been produced against the tubercle bacillus by inoculations of tuberculins of various sorts, but relative immunity has. Just as relative immunity has been produced in human beings against the entericas, bubonic plague, and many other diseases, but not absolute immunity; for instance, the relative immunity which is generally effective against bubonic plague is quite useless against the overwhelming infection of pneumonic plague. I do not think any method of inoculation with tuberculin will be effective against an overwhelming infection of tubercle bacilli in man, but fortunately cases of overwhelming infection are relatively few. The comparatively great protection to bovine bacilli produced in oxen by inoculation with living human bacilli encourages one to hope that an equally effective dead antigen is not beyond the bounds of possibility. It was just the ineffectiveness of the ordinary tubercular antigens that induced me to try for a better one; hence the benzoyl-chloride solution. Let me state my position with regard to the human problem again. For practical purposes it may be assumed that while everyone gets infected with tubercle bacilli only a small percentage develop disease from this infection. Presumably—I think a justifiable presumption—the majority do not develop the disease because their resistance is normal. If the resistance of those who would develop the disease could be made and kept normal the problem would be solved, for only those who got an overwhelming infection would develop the disease. I think there is reasonable hope of producing this relative degree of immunity with the benzoyl-chloride solution or other preparation of the tubercle bacillus, for I know that I can produce a sufficient degree of immunity in chronic pure infections of the tubercle bacillus, so that the patient completely and permanently recovers from his disease. I know, too, that this benzoyl-chloride solution produces its effects in very small doses. I have produced distinct focal and general reactions in pulmonary tuberculosis with a dose of 0·00000005 mg. The initial dose for these cases must not be larger than 0 0000001 mg. The highest dose that need usually be attained is 0 01 mg., while frequently 0 001 mg. is quite sufficient. So that if reactions are any criteria this antigen is much the most powerful ever produced. Further, I know that I can with precision restore delicate members of tubercular families, who are showing no physical or X ray signs of the disease, to ordinary vigorous health with this preparation. Have I not then some presumptive evidence that the benzoyl-chloride solution is a powerful and efficient antigen, and that it gives a reasonable hope of putting up a subnormal resistance to normal? I have done practically no animal experiments with the preparation. I would be exceedingly obliged to Dr. Cobbett if he would help me in this direction.

I quite see the great difficulty of proving absolutely the efficacy of preventive inoculation. The only proof that would satisfy myself would be the reduction of case incidence and mortality. In order to do this the trial would have to be large and prolonged. What arguments can be used to persuade those who have been exposed to virulent infection or have inherited a low resistance, such as members of tubercular families, to undergo the process? First, it can do them no harm, for it can be performed safely in those who are already infected. Secondly, it gives them a fair chance of making sure that their resistance is normal, so that they will be able to overcome an infection. Thirdly, if

they have got an active infection it will discover it, by the development of general or focal reactions or both, in its early stages when it can be certainly cured and with comparative ease. I should, of course, like to have compulsory preventive inoculation, but I quite realise that it is not practical politics at present.

Let me take now the prophylactic measures which Dr. Cobbett considers will be effective.

1. The amelioration of the conditions of life of the poor. The figures of the tuberculosis mortality of the Dublin registration area for 1915 will throw some light on this point. They are:—

Professional and independent classes	1·84 per 1000.
Middle class	2·18 ,,
Artisan and petty shopkeepers...	3·11 ,,
General service class	3·61 ,,

These figures clearly show that improvement of hygienic surroundings will not solve the problem, for have not the professional and middle class sufficiently good surroundings?

2. The cure of early cases. If he means by early cases cases giving physical signs in a part of a lobe and with tubercle bacilli in their sputum, I think I am right in saying that by sanatorium methods of treatment, the only generally recognised methods, the large majority do not lose their tubercle bacilli and are therefore not cured. If he means cases with no tubercle bacilli how is he going to diagnose them? By tuberculin reactions?

3. The isolation of those who are acting as sources of infection. I quite agree with him. This will have to be done. I would like to know from him how many beds will have to be provided in Great Britain; at least 20,000 beds will have to be provided in Ireland.

Two questions to Dr. Cobbett and I have finished this unavoidably lengthy letter. Does he think he can by isolation cut off entirely the sources of infection? If not, does he not think my proposal to supplement this measure by an attempt to produce a normal resistance in everyone to the tubercle bacillus worthy of consideration and trial?

I am, Sir, yours faithfully,

University College, Dublin, Nov. 27th, 1917. W. M. CROFTON.

SIR RICHARD CROFT AND THE CASE OF THE PRINCESS CHARLOTTE.

To the Editor of THE LANCET.

SIR,—In connexion with your annotation on the above subject in THE LANCET of Oct. 27th and Dr. Hingston Fox's letter in your issue of Nov. 24th, the following excerpt from the diary of my grandfather, Sir Alexander Morison, who, as a younger man, was appointed Physician-Extraordinary to Her Royal Highness and to her consort, Prince Leopold, may be of interest. This note has not previously been published and is as follows:—

Dec. 19th (1817).—Called on Dr. Baillie, who says the death of the Princess Charlotte was quite unexpected and not easy to be accounted for: for 3 hours after her delivery she was very quiet; then restlessness came on, tossing about and catching breathing, her pulses quick, intermitting, and low. Nothing but cordials could be given as wine, brandy, sp. ammoniæ. On opening the body about 2 ounces of water were found in the pericardium, which appears to have been poured out during her struggles, as the pulse gave no indication previously and (there was) no disease about the heart. About a pint of coagulated blood was found in the womb, but she had lost rather less than is common before, so that, upon the whole, she could not have lost more than 12 ounces above the usual quantity.

Dr. Hingston Fox considers the conditions mentioned confirm Playfair's inference that the cause of death was pulmonary embolism. It is, however, I think, more probable that the pint of concealed blood lost after an exhausting and disappointing labour (for the silence of the infant, if nothing else, must have apprised the mother of its death) proved sufficient to aggravate the cardiac failure notified by the "quick, intermitting, low" pulse referred to. The concord between uterine and cardiac tone post partum, irrespective of the amount of hæmorrhage, is a notable and interesting phenomenon even now not sufficiently recognised, and the loss of uterine tone in this case is shown by its pint-ful capacity. The silent and slow accumulation of blood in such an atonic uterus, even after perfectly normal, and it may be quick, delivery, and even after temporarily good uterine contraction, when unobserved, has been the cause of many an obstetric tragedy. Had the uterus of the Princess Charlotte been rapidly emptied and grasped the tone of both heart and womb might have been restored, with, or it might even have been without, the aid of the cordials mentioned. Pulmonary embolism—that is, thrombosis of the pulmonary artery—so soon after labour is, I think I am correct in stating, a very rare event. Indeed, although I cannot claim expert knowledge in such a matter, I am unaware of the record of any such case. Death under the circumstances seems to have been attributable less to the quantity of blood lost, however, than to the diastolic atony of the viscera. The stomach of the Princess is also stated to have contained *three pints* of fluid,[1] which is still further evidence of this concord both in tone and in atony in the viscera post partum, influenced by the common nervous system, to which I have referred. Some of this gastric fluid was doubtless introduced in the agonised efforts at rescue, the organ being too atonic either to reject or propel it. A satisfactory vomit under the circumstances is frequently associated with an immediate increase of both cardiac and uterine tone.

One must have a deep sympathy with all our brethren of that period engaged in this tragic case (although the every-day tragedy of the cottage is quite as harrowing as that tragedy of the palace), and all concerned seem to have acted to the best of their ability and knowledge. Croft was a fashionable accoucheur of the time and had attended many women of social position, such as the Duchess of Devonshire. Baillie was a sage physician and a noble man, whose mere relationship to Croft would not have secured the attendance of the latter in the case, and Sims was a well-known obstetrician; but none of them seem to have discovered the flaccid uterus reaching as high as the umbilicus as shown post mortem[3] and their efforts at restoration seem to have been limited to stimulation and necessarily so, for the later oxytocics were unknown and the organotherapeutic provocants of general visceral tone still far off in the womb of the future. As regards the grounds for Waldo's assertion of Croft's having been a Doctor of Medicine he may have seen a portrait with the M.D. attached. One such was engraved by W. Holl from a picture by Hayter of the year 1801. It was dedicated to Croft's memory and bears a legend eulogistic of his skill and humanity. As Dr. S. D. Clippingdale states,[4] however, beyond the "chirurgus privilegiatus," mentioned in the *Alumni Oxonienses*, there is no evidence of his having had any other medical degree or qualification.

I am, Sir, yours faithfully,

ALEXANDER MORISON.

Upper Berkeley-street, W., Dec. 1st, 1917.

THE CHRISTMAS APPEAL OF THE Y.M.C.A. TO MEMBERS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—The members of our profession in all parts of the Empire have given so generously of their skill, time, money, health, and life for the wounded and sick of our Navy and Army that it would seem almost an insult to ask further of them. The appeal, however, which is appearing in the leading London and provincial newspapers is a national one, and we would not wish to be left out of it, and, moreover, this appeal is for the many who are fighting or preparing to fight for us, and not only for those who are *hors de combat*. Our men are worth anything we can give them, and this appeal for £500,000 for the work of the Y.M.C.A. among them is practically equivalent to handing each man three shillings as Christmas-box.

Major W. McAdam Eccles, R.A.M.C.(T.), is willing to receive with thanks whatever sum members of the profession will send to his address, 124, Harley-street, W. 1, before Dec. 20th, 1917, and to hand it over as the contribution of our profession to this fund.

We are, Sir, yours faithfully,

DONALD MACALISTER, K.C.B.
ALFRED PEARCE GOULD, K.C.V.O.
CHARTERS J. SYMONDS, C.B.
Dec. 1st, 1917. W. MCADAM ECCLES, Hon. Sec.

Obituary.

ELSIE MAUD INGLIS, M.B., C.M.EDIN., L.R.C.P. EDIN.,

COMMISSIONER OF THE LONDON UNITS OF THE SCOTTISH WOMEN'S HOSPITALS (NATIONAL UNION OF WOMEN'S SUFFRAGE SOCIETIES).

THE death was recorded last week of Dr. Elsie Inglis, the Commissioner of the London Units of the Scottish Women's Hospitals, which took place on Nov. 26th at Newcastle-on-Tyne shortly after her arrival with her hospital unit from the Russo-Rumanian front.

Elsie Inglis was the second daughter of the late J. F. D. Inglis, a member of the Indian Civil Service, and formerly Chief Commissioner at Lucknow. She was born in 1865 and spent her early life partly in India and partly in Australia and was brought up in the strict tenets of the Plymouth Brotherhood. Determining to adopt medicine as a profession, she went to Edinburgh and qualified in medicine in 1892 as L.R.C.P. She studied also in Paris, Dublin, and Glasgow, and the Edinburgh degree becoming shortly afterwards available for women, Elsie Inglis, who had already gone into practice, graduated as M.B., C.M. Edin. in 1899. Her bent was strongly towards surgery, especially in its relation to the diseases of women, and she was shortly appointed surgeon at the Edinburgh Hospital and Dispensary for Women and Children, becoming also lecturer on systematic gynæcology to the School of Medicine in Edinburgh. In these positions she soon made herself apparent to all as a woman of professional capacity, great organising power, and high ideals. She encouraged in every way the women students in the Edinburgh Medical School, and was sincerely beloved as well as respected by those whose interests she was working to promote. She was an early and enthusiastic supporter of the movement for women's suffrage, and a prominent member of the Scottish Federation of Women Suffrage Societies, an association with practical politics which, while it gained for her friends and supporters in different directions, occasionally embarrassed her in her relations with some of her educational colleagues, not only those in the minority who did not share her views.

At the outbreak of war she originated the idea of sending to the actual seat of fighting hospital units staffed by women and organised by the Scottish Federation, and it was a great disappointment to her when it was decided by the authorities not to find place for these units on the British front. But the French and Serbian Governments gratefully accepted the proffered help, and Dr. Inglis with a large unit started a hospital at the Abbaye of Royaumont. This hospital was in full work by the first December of the war; its fine record has been chronicled publicly on many occasions, and to-day it is living up to that record. Returning to Scotland when the work in France had been successfully inaugurated, Dr. Inglis obtained permission to start for Serbia in April, 1915, and joined the units already working there as Commissioner to the Scottish Women's Hospitals. She took part in the tremendous fight against the typhus epidemic which threatened the army and civil population alike in the country of our tragic and courageous ally. She became devoted to the Serbians, whose simplicity and complete spirit of self-sacrifice for a cause appealed to her, and in her turn she was adored by the Serbians. She was the only woman on whom the Serbian Order of the White Eagle has ever been bestowed, but her real reward in Serbia was the unbounded gratitude with which the Serbian people received her work. When Bulgaria, or the King of Bulgaria, decided to fight on the side of the Turk, the betrayed Serbian army was forced to retreat, the Austro-German armies, thus reinforced, being able to overwhelm their one small foe, to whom no assistance could be given by her allies. Two hospital units were captured at Krushevatz, and Dr. Elsie Inglis and her colleague, Dr. Alice Hutchinson, together with part of the hospital staffs, who had refused to leave their badly wounded patients uncared for, were taken prisoners by the Austrians. All the hospital stores were looted, and the Serbian patients for whom they had been provided were sent into a deserted and filthy Serbian hospital to make room for the wounded of the conquerors. The hospital units were afterwards handed over to the Germans and finally released, proceeding to England through Switzerland in the spring of 1916. The full story of what had been accomplished by these brave and untiring women for the Serbians in their national agony will surely and in due time be recorded, but sufficient has been made public to enable all to see that no finer conquest of bravery over terror, sanitation over muck, and order over chaos will ever be told. "The Serbian nation," said the Crown Prince of Serbia, when decorating Elsie Inglis with the White Eagle and other of her brave comrades with the Order of St. Sava, "will never forget what these women have done"; their compatriots are not behind in their proud admiration.

Many people, not quite young, sorely tried by cruel experiences, marked by physical hardships, and definitely rewarded for great and acknowledged services, would have sought, for a time at least, a post of lesser personal responsibility, and even one more sheltered from actual risk. Not so Elsie Inglis. On her return she applied immediately to the War Office for permission to take a hospital unit to Mesopotamia. Her request was denied, and to grant it, indeed, would have been accompanied by insuperable difficulties. So her thoughts turned once more to her beloved Serbians, and with a field hospital unit of 75 women, the London units of the Scottish Women's Hospitals, she went out to Rumania with permission to travel by way of Archangel and Odessa. Here the hospital was attached to the Serbian Division of the Russian Army, a Slav corps organised to fight on the Dobrudja front, and Dr. Inglis faced once more the horrors of a great retreat before the invaders, this time of Rumania. For the work done on this ghastly occasion, both for the wounded soldiers, Russian and Serbian, and for the flying civilian population, the "ladies of the unit" were thanked by Mr. Balfour, as Secretary of State for Foreign Affairs. Advancing with the Russians when the armies again went forward, the hospital was re-established at Reni on the Russo-Rumanian front, where it worked at high pressure for nine months, until, in fact, all fighting ceased on that front. Then, and after a journey lasting four weeks across Russia, Elsie Inglis, the Commandant, brought the whole of her unit back in safety, only to die herself within a few hours of reaching England.

Elsie Inglis gave her life for her country and its allies as truly as any soldier in the trenches has ever done and as cheerfully. She was a wonderful compound of enthusiasm, strength of purpose, and kindliness, a threefold blend exactly calculated to allow full play to her great organising abilities. Remarkably modest, she was always full of generous appreciation of others. In the history of this world-war, alike by what she did and by the heroism, driving-power, and simplicity with which she did it, Elsie Inglis has earned an everlasting place of honour.

Dr. Inglis was buried in Edinburgh, the coffin being carried on a gun-carriage covered with a Union Jack and the Serbian flag, and the road to the cemetery was lined by crowds of citizens who had come together to show affectionate respect for her memory.

E. C. S.

EDWARD PARKER YOUNG, M.R.C.S. ENG., L.S.A.

Mr. E. Parker Young, who practised in the district for over half a century, died at his residence, Westbourne-square, Paddington, on Nov. 24th, in his eightieth year. He received his medical education at St. Mary's Hospital, and was house surgeon there after taking the usual double qualifications of the day—namely, the M.R.C.S., L.S.A., in 1860. Subsequently he was appointed surgeon to the Westbourne Infirmary. Mr. Young, who was a member of the first London County Council, was a Past Master of the Society of Apothecaries, and was until recently a member of the Central Midwives Board. He was formerly chairman of the Royal Medical Benevolent Fund and took an active part in the management of St. Mary's Hospital, the Lock Hospital, and various charitable and religious bodies. He was keenly interested in the working of the Young Men's Christian Association.

IN writing last week of the late Dr. Edward Burd's early memories, the name of Charles Darwin's father was inadvertently given as Erasmus. His father was Dr. Robert Waring Darwin, a successful physician practising in Shrewsbury. The error was not made by the writer of the obituary notice.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. A. B. Clarke, M.C., R.A.M.C., attached London Regiment, qualified at Aberdeen in April, 1915, and thereupon joined up. The award of the M.C. was recorded in THE LANCET of Nov. 18th, 1916, p. 881.

Died of Wounds.

Lieut.-Col. A. W. F. Sayres, R.A.M.C., received his medical education at St. Thomas's Hospital, London, and qualified in 1890. He held appointments at St. Thomas's Hospital, at the Bethlem Royal Hospital, and at the South Devon and East Cornwall Hospital, and prior to joining the R.A M.C. was tuberculosis officer to the Stonehouse District of the Devon County Council. Before the war he was attached to the Territorial Force Medical Service, in which he held the position of Major.

Wounded.

Capt. S. H. Harris, R.A.M.C., attached London Regt.
Capt. H. F. Woods, R.A.M.C., attached London Regt.
Capt. N. McA. Gregg, R.A.M.C., attached E. Yorks Regt.
Capt. C. Hunter, R.A.M.C.
Capt. A. J. A. McCabe-Dallas, R.A.M.C.
Capt. K. M. Nelson, M.C., R.A.M.C.
Capt. V. H. L. MacSwiney, R.A.M.C.
Capt. T. F. B. Reid, R.A.M.C., attd. Royal Field Artillery.
Capt. J. R. Barriskill, Australian A.M.C.
Capt. S. G. Gibson, Australian A.M.C.
Capt. T. C. Clarke, M.C., R.A.M.C.
Capt. T. Stansfield, R.A.M.C., attached Manchester Regt.
Lieut. M. B. Taylor, R.A.M.C.
Capt. J. Alexander, R.A.M.C.
Capt. C. B. Davies, M.C., R.A.M.C.
Lieut.-Col. H. W. Carson, R.A.M.C.
Major J. B. McKenzie, Australian A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported :—

Lieut. G. Hall, M.C., Royal Fusiliers, killed in action, son of Dr. A. Hall, of Surbiton, Surrey.
Major E. A. G. Snell, Bedfordshire Regiment and King's African Rifles, killed in action, only son of Dr. G. Snell, late Colonial Medical Service, of Earl's Court, London, S.W.
Lieut. J. C. Ensor, Welsh Regiment, died of wounds, second son of the late Dr. H. C. Ensor, of Cardiff.
Sergt. A. B. Bond, Australian Infantry, died in Prisoners of War Camp at Münster, Westphalia, son of Dr. J. W. Bond, of Harley-street, London.
Second Lieut. V. R. Atkinson, West Riding Regiment, killed in action, only surviving son of Dr. F. E. Atkinson, of Bowerley, Settle, Yorks.
Lieut. P. B. Clarke, Canadian Infantry, killed in action, only son of Dr. W. F. Clarke, of Toronto, Canada.
Lieut. C. L. Hains, R.N.A.S., reported missing on May 26th, now officially reported killed, son of the late Dr. L. J. C. Hains, of Totnes, Devon, and of Old Brompton, Chatham.

THE HONOURS LIST.

The following awards to medical officers are announced :—

Order of the British Empire.

Commander : Surg.-Lt.-Col. Sir W. R. Crooke-Lawless, C.B., C.I.E., Red Cross Hospital, Netley.
Officer : Lt.-Col. T. H. Symons, I.M.S., in charge of Hospital Ship *Madras*.

MENTIONED IN DESPATCHES.

The names of the following medical officers are mentioned for gallant conduct and distinguished services during the past six months in a despatch received from Lieutenant-General G. F. Milne, C.B , D.S.O., Commander-in-Chief of the British Salonika Force. All are members of the R.A.M.C. except where otherwise stated :—

Lt.-Col. (acting Col.) A. R. Aldridge, C.S.I., C.M.G.; Temp. Capt. D. I. Anderson; Lt.-Col. F. Ash; Temp. Capt. R. D. Attwood; Temp. Capt. J. Bain; Lt. (temp. Capt.) D. W. Beamish; Temp. Lt.-Col. E. T. F. Birrell, C.B., C.M.G.; Capt. G. B. Brand; Temp. Capt. A. Benjamin; Capt. A. E. Barnes; Capt. W. H. Brodie; Temp. Capt. M. S. Bryce, M.C.; Temp. Capt. (acting Lt.-Col.) C. V. Bulstrode (Maj. R.H.A.); Lt.-Col. H. J. M. Buist, D.S.O.; Temp. Capt. G. B. Burwell, M.C.; Capt. R. D. Cameron; Temp. Capt. L. Cassidy; Capt. T. Carnwath, Spec. Res. Capt. W. F. Christie; Capt. W. K. Churchouse; Capt. W. A. Clarke, Canadian A.M.C.; Temp. Capt. A. H. Coleman; Capt. (temp. Maj.) G. H. Colt; Capt. E. H. Coyne; Temp. Capt. P. C. Davie; Capt. B. L. Davis; Capt. I. D. Dickson; Temp. Capt. J. N. Dobbie; Lt. W. Donald; Temp. Lt.-Col. L. S. Dudgeon; Maj. P. G. Easton, D.S.O.; Capt. T. C. English, C.M.G. (temp. Col., A.M.S.); Temp. Capt. H. H. L. Ellison; Temp. Capt. R. R. Elworthy; Temp. Capt. H. R. Evans; Capt. H. A. T. Fairbank; Capt. (temp. Maj.) A. W. Falconer; Temp. Capt. D. Fettes; Temp. Capt. W. H. Fleetwood; Capt. W. B. Foley; Temp. Capt. J. G. Forbes; Maj. (acting Lt.-Col.) D. L. Fisher; Capt. W. R. Galwey, M.C.; Capt. J. S. Gaskell; Capt. E. G. Gauntlett; Lt.-Col. G. Gow, Canadian A.M.C.; Maj. (temp. Lt.-Col.) J. Gray; Capt. (acting Maj.) D. A. L. Graham; Temp. Capt. A. R. Green; Capt. A. D. Griffith; Capt. A. W. Harrington; Capt. N. H. Harrison; Temp. Capt. C. S. Van R. Harwood; Temp. Capt. J. F. C. Haslam; Capt. J. R. Hill; Temp. Capt. J. F. Hoare; Temp. Capt. H. G. Hobson; Lt.-Col. J. E. Hodgson; Capt. H. S. Hollis; Col. M. P. C. Holt, K.C.M.G., C.B., D.S.O.; Capt. B. Hughes; Capt. and Bt.-Maj. (acting Lt.-Col.) E. Johnson; Maj. J. G. W. Johnson, Canadian A.M.C.; Maj. J. T. Johnson, D.S.O.; Temp. Capt. J. M. Kelly; Capt. R. E. Kelly; Maj. (temp. Lt.-Col.) A. E. Kidd; Capt. G. F. V. Leary; Temp. Capt. A. A. Lees; Capt. W. A. Lethem; Capt. N. L. Lochrane; Capt. N. V. Lothian; Lt. (temp. Capt.) A. M. McCutcheon; Capt. D. Mallam; Capt. A. C. Macdonald, Spec. Res.; Temp. Capt. W. K. McIntyre; Lt.-Col. C. B. Martin; Capt. W. J. F. Mayne; Capt. P. H. Mitchiner; Temp. Capt. H. H. Moffatt; Capt. (temp. Maj.) K. W. Monsarrat; Temp. Capt. H. G. Murray; Lt.-Col. (temp. Col.) W. H. S. Nickerson, V.C., C.M.G.; Capt. O. J. O'B. O'Hanlon; Capt. A. Oliver; Lt.-Col. (temp. Col.) F. S. Penny, C.M.G.; Col. G. T. Rawnsley, C.M.G., A.M.S.; Temp. Capt. D. R. E. Roberts; Capt. A. B. Schinbein, Canadian A.M.C.; Capt. L. J. Shell; Lt.-Col. and Bt.-Col. (temp. Col.) F. Smith, C.M.G., D.S.O.; Lt.-Col. L. F. Smith, C.M.G.; Lt.-Col. R. H. Starling, F.R.S.; Capt. J. P. Stewart, C.B. (temp. Col., A.M.S.); Temp. Maj. J. W. Struthers; Capt. (acting Lt.-Col.) P. S. Tomlinson; Capt. R. M. Vick; Maj. E. B. Waggett; Maj. (acting Lt.-Col.) J. Ward; Temp. Capt. J. D. Watson; Temp. Capt. T. B. Williams; Capt. M. J. Williamson, M.C.; Capt. E. A. Wilson; Temp. Capt. D. E. S. Wishart; Lt.-Col. S. H. Withers, C.M.G.

MEDICAL WOMEN (ATTACHED R.A.M.C.).

Miss M. A. Blair, Miss B. M. Cunningham, Miss E. J. Dalyell, Miss E. M. Edwards, Miss E. B. Hollway.

The names of the following medical officers, serving with the British artillery in Italy, have been brought to the notice of the Secretary of State for War for distinguished service in the field :—

Capt. J. A. Davies, R.A.M.C. (T.F.); and Maj. (temp. Lt.-Col.) B. H. V. Dunbar, D.S.O., R.A.M.C.

RELEASE OF MEDICAL STUDENTS.

The scope of the Army Council's Instruction of September is extended by the new Order (No. 1751) which provides for transfer to the reserve or discharge from the Army, on application, of any medical student who had at the time of enlistment completed the second year of his professional course. Release is conditional upon resuming medical studies, enrolling in an O.T.C., and passing the examination in anatomy and physiology within six months.

BATHING TRAINS FOR THE AUSTRO-HUNGARIAN ARMY.

In the *Military Surgeon* (Washington, D.C, U.S.A.) for October Colonel Joseph H. Ford, Medical Corps, United States Army, describes a bathing train used in the Austro-Hungarian Army. Its arrangement, he says, gave great satisfaction, and ten other similar trains were in use with the enemy forces. In addition to the usual locomotive for transport it had another altered to pump water and supply steam for disinfection and for warming the bath water. Two living cars housed the personnel (1 second lieutenant, 6 train crew, 17 technical staff). Five store cars carried soap, towels, brushes, 10 per cent. naphthalin ointment in vaseline, 10,000 clean clothing outfits for men to wear while their own was being disinfected. Water for two days was carried in two tank cars, each holding 40 tons. There were three disinfecting cars, of which one disinfected underclothing at 103° C. in half an hour; the other two disinfected furs, overcoats, boots, &c., with formalin at 60° C. in six hours. There were five cars in the bathing section. Men undressed in the centre car, putting each his kit in a sack, taken away at once for disinfection, and themselves they passed into the next car either way, where each picked up soap and towel and washed himself. The bath car had a 25-ton tank on the roof, and 30 shower douches allowed seven gallons of water at 98° F. to fall on each of the 30 bathers in five minutes, by the end of which time he was supposed to be clean. The car was lighted by numerous frosted windows or by overhead electric lights. The man then dried himself and rubbed himself over, especially the hairy parts, with the 10 per cent.

naphthalin ointment and passed into the next car, where he dressed himself in the outfit laid ready for him, remaining there till his own clothes were disinfected and he could change into them. Each train was estimated to bathe 1400 to 2000 men daily, but one, says Colonel Ford, had been known to deal with 3600. Sometimes the bathing train had a laundry attached; more usually the laundry was independent, and carried by a motor lorry with trailer. It had a washing machine, centrifugal drier, drying closets, and a mangle; with 23 men as staff, they were expected to wash a ton of dirty clothes in a day.

PRACTICES OF ABSENTEE MEDICAL OFFICERS.—The following two resolutions were passed at a meeting of the medical profession in the Southampton area during the summer and are now sent to us for publication by Dr. H. L. Hamilton, honorary secretary of the Local Medical War Committee:—

1. In view of the difficulty of the "remaining" doctors getting accurate information, this meeting recommends that each "absent" doctor, on his return to Southampton, should call on his old patients and obtain from them particulars of their having consulted any "remaining" doctor, and the "absent" doctor should be and is hereby authorised to make application to the "remaining" doctor for particulars of any attendance given, and for payment of the half fees earned, and that all doctors be so informed.

2. This meeting recommends that the individual members of the profession should, owing to the difficulty of selling a practice, pay to the representative of any absent doctor (general practitioner) who dies on service, or to himself if permanently and totally disabled on service, £10, if such dead or disabled practitioner was in practice on his own account, or £5 if in partnership, and that all doctors be so informed.

It was resolved with regard to resolution No. 2 that it should apply to general practitioners only, and that the benefits should apply to those general practitioners absent from the town and from their practices. It was also agreed that the widow of any doctor who received the benefit should have the right unprejudiced, so far as the grant would be concerned, to sell the practice.

Medical News.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on Nov. 13th, 35 cases were considered and £330 voted to 33 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 38, of M.R.C.S. Eng. who practised at Oxford and died in January, 1917. Applicant was left with five children, ages 10 months to 13 years, and with exception of £1100 capital is dependent on relatives, who cannot do very much. Wants help for the education of the children. Voted £20 and referred to the Guild.—Daughter, aged 56, of M.R.C.S. Eng. who practised in North Wales and died in 1913. Applicant was teaching in Austria when the war commenced and lost practically all her belongings. Only certain income £21 per annum, and this year has been living on a legacy of £60 left her by a relative. Health has been very indifferent of late. Voted £10 and referred to the Guild.—M.B. Edin., married, who has practised at Colchester and London, and is now suffering from cancer. Before the war was making £1000 a year, and owing to the war and illness this was reduced up to three months ago to about £350. Quite unable to work now and living on fees owing to him. Rent £200 a year. Has a daughter and one son, who is in the Army. Voted £5 and the case to be further considered.—Daughter, aged 52, of L.S.A. Lond. who practised at London and Eastbourne and died in 1882. Applicant and her mother lived together until the death of the latter in July of this year, and several small items of income died with her. The applicant has a small school, the profit from which is about £25 a year. Her other income is from investments bringing in about £14 a year. Voted £10 in 2 instalments.—Daughter, aged 34, of M.R.C.S. Eng. who practised in Yorkshire and Bedford and died in 1906. Applicant has been a chronic invalid all her life, and her brother-in-law has kept her since her father's death, but owing to illness and loss of income he cannot do so entirely now. She would like to get into a home. Voted £18 in 12 instalments.—Widow, aged 41, of L.R.C.P. Edin. who practised at Middleham and died on Oct. 3rd, 1917. Applicant left with two children, ages 14 and 9. Wants help for the education of the children. Will get a little from insurance and wants to sell the practice. She hopes to be able to obtain some employment when her affairs are settled. Voted £10 and referred to the Guild.—Daughter, aged 65, of M.R.C.S. Eng. who practised in London and Birmingham and died in 1856. Applicant tries to make a living by sewing, but owing to bad health and the increased cost of living is unable to pay her way. Relieved three times, £36. Last time, March, 1913. Voted £12 in 12 instalments.—Widow, aged 46, of L.R.C.P. Edin. who practised in East London and died in 1915. Applicant was left entirely without means, with one son, now aged 8 years. She is paralysed and unable to do anything. A relative who found her lodgings has recently died, and she is now living in a room at an almshouse paying 2s. per week. Relieved once, £10. Voted £15 in 12 instalments.—Widow, aged 36, of L.R.C.P. Edin. who practised in Edinburgh and died in 1916. Applicant was left with four children, ages 3–11, with an income of £96 a year. Owing to the increased cost of living she finds it quite impossible to manage. Relieved once, £12. Voted £15 in 12 instalments.—Widow, aged 59, of L.R.C.P. Edin. who practised at Langley and died in 1909. Lives in own house, which is heavily mortgaged. Endeavours to make a living by taking in paying guests, but owing to high price of living unable to make ends meet. Relieved seven times, £70. Voted £10 in two instalments.—Widow, aged 60, of M.D. Glasg. who practised in Perthshire and died in 1907. Her total income, from a lodger and other sources, £73. Son who helped to keep the home together now in the Army. Relieved three times, £22. Voted £10.—Widow, aged 71, of L.R.C.P. Edin. who practised at Cardiff and died in 1906. Receives two pensions from other societies, making her income £54. Pays £1 per week for board and lodging. Two sons married and unable to help. Suffers from rheumatism and bronchitis. Relieved 12 times, £88. Voted £6 in 12 instalments.—Daughter, aged 47, of M.R.C.S. Eng. who practised at Redcar and died in 1873. Applicant suffers from tuberculosis and lives with mother, who is unable to help her. She receives two pensions from other societies, total £30. Relieved six times, £62. Voted £10 in two instalments.—M.R.C.S. Eng., aged 48, married, who has practised at Birmingham. Applicant suffers from disseminated sclerosis and is quite helpless. Only income 10s. a week from relatives. Only son recently elected to an Epsom College scholarship. Relieved once, £18. Voted £26 in 12 instalments.—Widow, aged 72, of M.R.C.S. Eng. who practised at East London and died in 1913. Applicant's income is £50, and this is all she has to support herself and daughter. A brother who used to help has recently died. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 47, of L.R.C.P. Edin. who practised at Longelly and died in 1913. Has five children and only two able to assist, they providing £95 a year. One son in the Army and no separation allowance. Increased cost of living makes it impossible for her to manage. Relieved twice, £30. Voted £10 in two instalments.—Widow, aged 54, of M.D. Edin. who practised at Newcastle and died in 1896. Applicant left without means. She obtained work, but fractured her leg some time ago, and has been incapacitated since. Has a daughter who is a widow and works as a clerk, and helps as far as possible. Relieved three times, £36. Voted £12 in 12 instalments.—Daughter, aged 65, of F.R.F.P.S. Glasg. who practised at Widnes and died in 1863. Applicant has two pensions bringing her in £40 a year, and is provided with furnished rooms. Her health is very bad and requires special nourishment. Owing to high price of food, finds it difficult to manage. Relieved four times, £20, the last time in May, 1914. Voted £5.—M.R.C.S. Eng., aged 47, married, who practised in London and other places. Applicant has suffered from asthma for a number of years. He joined the R.A.M.C., but after a few months was invalided out. Now totally incapacitated from work, and his wife, who had obtained a post, had to give it up to nurse him. All savings practically exhausted. Voted £20, and recommended to apply to another Fund, from which a little help has been given.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W.1.

A WELSH WAR MEMORIAL.—On Nov. 30th Mrs. Lloyd George presided at Shrewsbury over a conference called to promote a fund for the welfare of sailors and soldiers of Wales as a Welsh war memorial. The scheme will unite the Welsh National Fund and the National Fund for Welsh Troops. The Prince of Wales is naturally suggested as the patron of the fund. It is proposed that in order to provide free education at the University of Wales for the sons and daughters of soldiers who have sacrificed themselves for their country a science institution be built at Bangor at a cost of £150,000.

UNITED PROVINCES HOSPITALS.—The United Provinces Government's resolution on the report on hospitals for the years 1914 to 1916 says that from the outset of war heavy and continuous demands were made on the personnel, which has been depleted to an extent unknown in any other branch of the public service. Three-quarters of the Indian Medical Service officers on the civil employment list, and practically all the military assistant surgeons and sub-assistant surgeons, have been transferred to the military service. The expansion of medical activities, which the report nevertheless reveals, is the best testimony to the success with which the department has been administered in circumstances of exceptional difficulty. The thanks of the Government are due to those officers for whom retention in civil employ has meant a heavy increase of work, and to those who have given up private practice or the enjoyment of pension in order to set others free for military service.

SECOND ANNUAL REPORT OF THE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.—This report contains the record of another year's successful work in providing accurate and enlightened information as to prevalence of venereal diseases and promoting reforms in connexion with them. It includes the addresses delivered by Lord Rhondda, Sir Alfred Keogh, the Lord Mayor of Liverpool, Mrs. Creighton, and Sir Malcolm Morris at the annual meeting in the Queen's Hall on June 13th. During the year ending June, 1917, branch committees of the council had been formed at Bath, Birmingham, Cambridge (co.), Dewsbury, Gloucester, Leicester, Liverpool, London and Home Counties, Newcastle-upon-Tyne, Southport, South Shields, and Tynemouth, where in each case a treatment scheme had been approved by the Local Government Board, and at Bournemouth, Walsall, and York, where some provision for treatment had been made but a scheme not yet approved. An account follows of the work being done by each of these branches, a list of books and pamphlets which have received the imprimatur of the council, and, in an appendix, the terms of the Venereal Disease Act, 1917.

METROPOLITAN HOSPITAL SUNDAY FUND.—The total receipts for this year of the Metropolitan Hospital Sunday Fund now amount to £76,354, or £5655 more than the sum collected last year. There are 239 hospitals, dispensaries, and nursing institutions receiving benefits from the Fund.

DONATIONS AND BEQUESTS.—The late Mr. John William Roberts, of The Dingle, Hale, Cheshire, has left by will £1000 to the Manchester Royal Infirmary and £500 each to the Manchester and Salford branch of the Society for the Prevention of Cruelty to Children, the Incorporated Cheshire and Lancashire Society for the Permanent Care of the Feeble-minded, the National Institution for the Blind for work among blinded sailors and soldiers at St. Dunstan's, and the Crippled Children's Help Society.—By the will of the late Mrs. Ellen Woodgate McMillan Guy's Hospital will receive £2000.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A quarterly meeting of the association was held on Nov. 27th, under the presidency of Lieutenant-Colonel David G. Thomson, R.A.M.C. The appointment of Dr. James Chambers, of Roehampton, as treasurer, in the place of Dr. Hayes Newington, was announced by the chairman, who said that on the same day two of the great pillars of the association, Dr. Newington and Dr. A. R. Urquhart, had died. The meeting marked its sense of bereavement by rising to pass the resolution of condolence to the respective relatives. A similar mark of respect was shown in regard to the following deceased members: Dr. William Graham, medical superintendent of Belfast District Asylum (the result of an accident), and Colonel James Hyslop, D.S.O., Deputy Director of Medical Services, Pietermaritzburg. Dr. David Orr and Major R. G. Rows, R.A.M.C., contributed a paper, with lantern demonstrations, on Experimental Toxi-infections of the Central Nervous System.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

C. V. Samwell to be temporary Surgeon.

ARMY MEDICAL SERVICE.

Assistant Director of Medical Services: Temp. Col. J. A. Roberts, C.B., Canadian A.M.C., vice Temp. Lieut.-Col. J. McCombe, Canadian A.M.C.

Col. F. R. Newland, C.M.G., to be temporary Surgeon-General.

TERRITORIAL FORCE.

Major (temp. Lieut.-Col.) **T. Kay** to be Assistant Director of Medical Services, and to be Temporary Colonel whilst so employed.

Temp. Col. W. C. Beevor, C.M.G. (Lieut.-Col., retired pay), relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services, and is granted the honorary rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Temp. Lieut.-Col. (acting Col.) J. D. Courtenay, Canadian A.M.C., relinquishes the acting rank of Colonel on ceasing to be Officer Commanding of a Canadian Hospital.

Temp. Major G. D. Gray, M.D., to be acting Lieutenant-Colonel whilst in command of the Chinese General Hospital.

Major T. B. Moriarty and Major J. F. Whelan to be acting Lieutenant-Colonels whilst in command of a Medical Unit.

Temporary Lieutenants to be temporary Captains: N. S. Neill, D. F. Riddell, H. L. Martyn, L. D. Cohen, L. W. Kergin, A. F. Cowan, S. G. Kean.

Lieutenants to be Captains: E. M. L. Morgan, H. Morley, R. F. Jarrett, J. W. G. Steell, C. Young, A. W. A. Davies, A. R. Balmain, G. S. Martin, B. H. Simon, G. S. Lawrence.

The undermentioned to be temporary Captains: D. A. Warren, M.C., J. C. Bawden, C. H. Philips, G. M. Shaw, J. T. MacKenzie, A. Drouin, H. M. Godfrey.

Temporary honorary Lieutenants to be temporary honorary Captains: A. T. Paterson, of the St. John's Ambulance Brigade Hospital; C. H. L. Harper.

C. G. L. Wolf to be temporary Honorary Captain whilst specially employed.

T. O. Hutton, late temporary Captain, is granted the honorary rank of Captain.

To be temporary Lieutenants: S. G. Kean, A. G. McKenley, H. J. Starling, C. W. Joynt, L. H. Butler, F. W. H. Pilot, T. B. H. Tabuteau, B. W. H. Fergus, J. G. Millar, W. S. Stevenson, R. Butterworth, J. C. Nixon, A. G. Wright, H. J. Villiers, J. C. Fox, G. H. U. quhart, H. S. Metcalfe, J. A. M. Bligh, H. L. W. Woodroffe, R. Steel, B. S. Laurence.

Officers relinquishing their commissions: Temp. Capts. R. N. Craig, A. E. W. Idris, C. Weeks (granted the honorary rank of Captain), N. McGowan, S. Pinion, A. J. Best, L. Cadins, J. H. O'Neill, W. R. W. Asplin, D. H. Pennant, D.S.O., C. E. Price, E. H. Roberts, R. B. Martin, M.C., D. D. Rosewarne, R. Silcock, A. W. Addinsell, E. R. Edson, Canadian A.M.C., J. D. Maclean, Canadian A.M.C., H. W. M. Kendall, W. S. Holmes, Canadian Army Dental Corps, Temp. Hon. Capt. E. M. Eaton (on ceasing to be employed with a Red Cross Hospital), Temp. Lieuts. H. A. Faulkner, J. H. P. Vivian, P. A. Storey, P. Maguire, W. H. Kirk, H. Nicol (on account of ill-health), Temp. Hon. Lieut. F. A. Simonds.

SPECIAL RESERVE OF OFFICERS.

Samuel Murdock Riddick, M.B., to be Lieutenant.

G. G. Allan (from Edinburgh University Contingent O.T.C.), L. C. Moore and J. W. Brash (from University of London O.T.C.), C. Magee (from Glasgow University Contingent O.T.C.).

TERRITORIAL FORCE.

To be acting Lieutenant-Colonels whilst commanding Stationary Hospitals: Major J. W. Mackenzie, Major I. B. Yeoman.

Major J. A. Coupland, from permanent personnel, to be Major, whose services are available on mobilisation, and is restored to the establishment.

Major (temporary Lieut.-Col.) J. H. Ray relinquishes his temporary rank, and is restored to the establishment.

Major (temporary Lieut.-Col.) R. M. West, D.S.O., to be Lieutenant-Colonel.

Major (temporary Lieut.-Col.) A. Cooke relinquishes his temporary rank and is restored to the establishment.

The undermentioned Captains (temporary Majors) relinquish their temporary rank, and are restored to the establishment: R. Overshaw, F. E. Tylecote.

Capt. G. M. A. Thomas resigns his commission on account of ill-health.

Capt. H. F. Wilkin, M.C., F.R.C.S., is restored to the establishment on vacating the appointment as Deputy Assistant Director of Medical Services.

Capt. J. D. Allen resigns his commission on account of ill-health.

Capt. J. S. Burton resigns his commission.

Capt. A. S. Daly is seconded for duty with a General Hospital.

Capt. A. Gough, Capt. M. Horne, Capt J. Wharton, and Capt. T. C. de Bonnville are restored to the establishment.

Capt. H. W. Beedham and Capt. W. W. Horton resign their commissions on account of ill-health.

Capt. E. Bromet and Capt. B. Fawssett relinquish their commissions on account of ill-health contracted on active service, and are granted the honorary rank of Captain.

Lieut. S. R. Walker to be Captain.

Capt. J. Broadly and Capt. H. Mason are seconded.

Capt. (temp. Major) J. M. Hunt to be acting Lieutenant-Colonel whilst performing the duties of Administrator of a General Hospital.

Capt. R. P. Pollard, from Attached to Units other than Medical Units, to be Captain.

Capt. F. W. C. Brown is seconded whilst holding an appointment as Deputy Assistant Director of Medical Services.

Capt. D. Shannon to be acting Lieutenant-Colonel whilst commanding a Stationary Hospital.

Capt. (temp. Major) J. W. Keay relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. E. B. Argles is seconded whilst holding an appointment as Deputy Assistant Director of Medical Services.

Capt. J. F. Edmiston from Deputy Assistant Director of Medical Services, to be Captain.

Capt. (temp. Major) W. Cowie relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Major.

Captain W. Brown to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (acting Lieut.-Col.) W. Brown relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. J. MacMillan, M.C. to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. H. Armstrong and Capt. W. C. Oram are restored to the establishment.

Captains (temporary Majors) relinquishing their temporary rank are restored to the establishment: D. Douglas-Crawford, J. Hay.

Lieut. S. R. Walker to be Captain.

C. B. Palmer to be temporary Lieutenant-Colonel, Northumberland Medical Volunteer Corps.

INDIAN MEDICAL SERVICE.

Lieut.-Col. W. W. Clemesha to be temporary Colonel whilst employed as Assistant Director of Medical Services.

URBAN VITAL STATISTICS.

(Week ended Dec. 1st, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was equal to 11·9, against 12·2 and 12·5 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 12·0, or 1·1 per 1000 less than that recorded in the previous week; among the remaining towns the rates ranged from 3·7 in Warrington, 4·8 in Ealing, and 5·1 in Ilford, to 18·2 in Stockton-on-Tees, 19·1 in St. Helens, and 20·4 in Brighton. The principal epidemic diseases caused 307 deaths, which corresponded to an annual rate of 0·9 per 1000, and included 122 from measles, 65 from infantile diarrhœa, 57 from whooping-cough, 48 from diphtheria, 13 from scarlet fever, and 1 from enteric fever. Measles caused a death-rate of 1·6 in Burnley, 1·8 in Brighton, 2·7 in Acton and in Stockton-on-Tees, 2·9 in St. Helens, 3·4 in Leicester, and 5·0 in Dewsbury. The 1344 cases of scarlet fever and 1657 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 29 and 79 above the numbers remaining at the end of the previous week. Of the deaths from all causes in the 96 towns, 150 resulted from violence. The causes of 24 deaths were uncertified, of which 7 were registered in Birmingham and 3 each in Leicester, Birkenhead, Gateshead, and Rhondda.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 12·5, against 11·9 and 12·2 per 1000 in the two preceding weeks. The 271 deaths in Glasgow corresponded to an annual rate of 12·7 per 1000, and included 6 each from measles and diphtheria, and 3 each from whooping-cough and infantile diarrhœa. The 62 deaths in Edinburgh were equal to a rate of 10·7 per 1000, and included 1 each from measles and infantile diarrhœa.

Irish Towns.—The 119 deaths in Dublin corresponded to an annual rate of 15·6, or 0·6 per 1000 above that recorded in the previous week, and included 4 from infantile diarrhœa, 3 from measles, 2 each from enteric fever, whooping-cough, and diphtheria, and 1 from scarlet fever. The 105 deaths in Belfast were equal to a rate of 13·9 per 1000, and included 3 from diphtheria, 2 from infantile diarrhœa, and 1 each from measles and whooping-cough.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Health Insurance Bill.

A Standing Committee of the House of Commons is now engaged in the consideration of the details of the National Health Insurance Bill. Some progress has been made with the measure at two sittings.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 28TH.

Panel Practitioners and Confinements.

Answering Mr. BOWERMAN, Sir E. CORNWALL, representing the National Insurance Commissioners, stated that the services of a medical man in attending during childbirth upon an insured person were not amongst those which the panel doctor was under any agreement with the Insurance Committee to provide. The question of making provision under national health insurance for medical attendance for insured women at confinement would not require legislation. He recognised the importance of the need for this extension of insurance medical services, and he was giving it earnest consideration at the present time.

Prisoners of Feeble Mind.

Sir W. COLLINS asked the Home Secretary whether his attention had been called to the reports of the Prison Commission and of the Medical Commissioner deploring the want of provision of accommodation under the Mental Deficiency Act for prisoners found to be of unsound or feeble mind and the consequent retention in prison amid criminal surroundings.—Sir G. CAVE wrote in reply: State institution for defectives had been provided at Moss Side where it would have been possible to accommodate a large number of defectives on transfer from prison, but just when it was completed the urgent need of the Army Council for hospital accommodation made it necessary to find these premises for use as a military hospital. In place of Moss Side a State institution for women has been established at Farmfield, and proposals are now under consideration for opening another temporary State institution for men and women. That more accommodation has not already been provided is due to conditions arising from the war, including the difficulty of obtaining suitable male attendants.

Organisation of Medical Volunteer Corps.

Sir W. COLLINS asked the Under Secretary for War what progress had been made with the organisation of medical volunteer corps and field ambulances; in how many counties England and Wales such corps had been formed; and what organisation it was proposed to set up in the case of the County of London.—Mr. MACPHERSON replied: Sixteen county medical volunteer corps have been formed or are in process of formation. The total number of field ambulances provided by these corps is 29. No medical volunteer corps has yet been formed for the County of London, but it may be possible to utilise the services of certain personnel in the County of London if developments which are under consideration mature.

MONDAY, DEC. 3RD.

Remuneration of Grimsby Panel Practitioners.

Mr. TICKLER asked the Representative of the National Insurance Commissioners whether he was aware that the Grimsby doctors had now received a final settlement of their remuneration under the national insurance; that their claims amounted to £9256 10*s.*, and that, after deducting £8 9*s.* 10*d.* for various reasons, they had only been paid £529 6*s.* 7*d.*, leaving an unpaid balance of £2138 13*s.* 7*d.*; and could he say when this balance would be paid.—Sir E. CORNWALL replied: I am not aware that any such balance remains unpaid. Perhaps my honourable friend would be good enough to communicate with me as to the sum which he mentions as the amount of the doctors' claim, as I do not understand it. The practitioners have received the full sum now due to them under their respective agreements with the Insurance Committee so far as known to the Department.

R.A.M.C. Officers in India.

Mr. MACPHERSON (Under Secretary for War) replying to Mr. BUTCHER, wrote: The War Office has taken steps to relieve from time to time certain medical officers who have been a long time in India, and is continuing the process, which is necessarily slow owing to difficulties of transport.

TUESDAY, DEC. 4TH.

Death of Sir Stanley Maude from Cholera.

Replying to Mr. CHANCELLOR, Mr. MACPHERSON (Under Secretary for War) said: I regret to state that it is confirmed that Sir Stanley Maude died of cholera.

Mr. CHANCELLOR asked whether there many cases of cholera in Mesopotamia.—Mr. MACPHERSON: I am glad to say that there are very few cases indeed.

Glycerine and Sugar in Prescribing.

Mr. ANDERSON asked the President of the Local Government Board whether he was aware that the British Medical Association and the Pharmaceutical Society had issued a formulary containing pharmaceutical preparations known as glycerines which were devoid of glycerine and syrups free from sugar; and whether, considering that the formulary was to come into use on Dec. 1st, he would issue instructions to local authorities to take samples of dispensed medicines with a view of submitting them to examination by public analysts.—Mr. PRATT (for Mr. HAYES FISHER) replied: The answer to the first part of the question is in the affirmative. The attention of public analysts has already been drawn to the fact that the General Medical Council has found it necessary to withdraw certain medicinal preparations from the British Pharmacopœia owing to the need for economising in the use of glycerine and sugar. It does not appear to my right honourable friend that any further action on his part is necessary. He is advised that the omission of sugar and glycerine from the preparations in question does not materially lessen their value as medicines.

Mr. ANDERSON asked a somewhat similar question of the Representative of the National Insurance Commissioners, inquiring whether he would take immediate steps to remind Insurance Committees that insured persons were entitled to have genuine medicines prescribed and dispensed for them, and that samples should be taken of dispensed medicines with a view of submitting them to examination by public analysts.—Sir E. CORNWALL replied: I understand that the General Medical Council has deleted from the British Pharmacopœia certain preparations containing glycerine or sugar owing to the importance in the public interest at the present time of restricting as far as possible the medicinal use of these substances to purposes for which efficient substitutes are not available. Alternative preparations have accordingly been formulated in the publication referred to. That document did not require the approval of the Insurance Commissioners. I would remind the honourable Member that it is the duty of every doctor attending an insured patient to prescribe the proper and sufficient drugs and medicines that are necessary for the efficient treatment of the case, and this is in no way affected by the issue of the formulary in question. The Commissioners are not aware of any reason for issuing such a communication to Insurance Committees as the honourable Member suggests.

WEDNESDAY, DEC. 5TH.

American Medical Men in Military Hospitals.

Mr. LYNCH asked the Under Secretary for War whether medical men in military hospitals who were over age had been replaced by Americans; if so, to what extent this practice had been carried on; and whether he would consider the possibility of utilising the services of elderly medical men for the examination of recruits so as to release for active service medical men of military age.—Mr. MACPHERSON answered: The services of medical officers of the Army of the United States of America are being made use of in the military hospitals at home and abroad, not only to release medical practitioners required for the Army, but in order to afford these officers opportunities of acquiring practical military experience with troops under service conditions. The examination of recruits is conducted under the instructions of the National Service Ministry, to whom this part of the question should have been addressed.

Mr. LYNCH: Is the honourable gentleman aware that there are many civil practitioners over military age who are anxious to do the work?—Mr. MACPHERSON: We always try to use the services of civil practitioners. There was at one time a complaint in the House that we were using civil practitioners too much.

CLARKE.—On Oct. 28th, killed in action, Lieutenant Paul Brooks Clarke, 124th Canadian Pioneers, only son of Dr. and Mrs. W. F. Clarke, of 2132, Queen-street East, Toronto, Canada, aged 21.
GALSWORTHY.—On Nov. 28th, Laurence Galsworthy, M.R.C.S., L.R.C.P. Lond., aged 47 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

MATCHES AND PINS.

WITH reference to a recent statement in the House of Commons by Mr. Wardle, Parliamentary Secretary to the Board of Trade, that there are enough matches to go round if each adult will confine his consumption to six matches a day, a statistical minded correspondent writes:—Matches and pins are so indispensable to-day that it is difficult to realise that there was a time when they were not used. Nevertheless, the present shortage of matches and the possible rise of prices in pins, with the consequent need of economy, take our thoughts back to that period. The use of both matches and pins is comparatively modern. As regards matches, although Germany is given the credit for progress in match making, starting in 1680 with one Haukwitz, the first really practical friction matches were made in 1827 in England by John Walker, a druggist, of Stockton-on-Tees, although before that time chemical matches had been made on a small scale which required to be dipped in sulphuric acid to ignite. In 1852 safety matches were made by Lundström, a Swede, and for many years after then were known to almost everybody by the name of "Tandstickers," a corruption of the Swedish name for matches. Although safety matches are supposed only to strike on the box, they will ignite if held against a hot piece of metal such as a hot stove or even rubbed with a swift long stroke on glass. A chlorate of potash tablet rubbed on a safety match-box will light the gas, and so will the spark from a patent metal pocket lighter which happens to have run dry of benzine. Vestas, which are only lengths of fine taper fitted up as matches, although expensive, perhaps may by care be made economical, as if saved after use they can be used again as short tapers for obtaining lights from gas burners. A wax vesta after one short use may, indeed, be used as a tiny candle by splitting the end crosswise to make four feet and standing it on a penny—a light for an emergency.

In October, 1626, in the reign of Charles I., John Tilsby established a pin-making industry, employing a number of people, although brass pins were first brought from France in 1540 and first used in England by Catherine Howard, the wife of King Henry VIII. Indeed, an Act of Parliament was passed for the true making of pins, 34 and 35 Henry VIII. (1542-3) c. 6, but was repealed by 37 Henry VIII. c. 15. To France is due the elegance of the pin, to America about 1830 its modern improvement. Before then several people were employed in making one pin by 14 to 20 distinct operations, but a machine afterwards made them in one. The number of pins used is huge. In 1880 in England the supply was 9 per inhabitant per week; in 1850 it was only 4.

THE CRY OF THE CHILDREN.

"The Robin Society," 421, New Cross-road, London, S.E. 14, of which the King is a patron and whose object is to provide free meals in the winter time, particularly at Christmas-tide, for the very poorest children in the metropolis, makes an earnest appeal for funds. The conditions imposed on the destitute and needy by the war have increased the hard lot of the ill-nourished children of our mean streets, while the funds available for assistance have been smaller, owing to the many extra calls upon charity. But sympathy with suffering demands help, and it must be remembered that the future vitality of the nation depends upon the conservation of the child-life of to-day. In addition to money, clothing of all kinds is urgently needed, and children's games and books and used Christmas-cards are required for the holiday home of the society. Cheques and postal orders should be made payable to "The Robin Society" and crossed London County and Westminster Bank, Ltd., Deptford Branch. The society is unsectarian.

ARTIFICIAL LIMBS.

THE need which has been created as a result of the war has inevitably stimulated the invention, improvement, and production of artificial limbs, and medical men will find the catalogue issued by Mr. F. G. Ernst, 80 and 82, Charlotte-street, London, W. 1, orthopædic mechanician to the National Orthopædic Hospital and other institutions, a useful book of reference. It is a well-illustrated and printed quarto book of 66 pages, and describes in clear language and by diagram and reproduced photographs the mechanical action, not only of artificial limbs, but also of numerous accessory appliances for enabling the wearer to feed and dress himself, shave, smoke, hold a pen, play billiards, handle coins and tools, and attend to lavatory requirements. Instructions

as to the taking of "casts," hints on the use of artificial limbs, and details for measurement when ordering are also given.

NATIONAL BABY WEEK COUNCIL.

THE report of this council, which has just been issued, contains an account of the activities of the organisation during Baby Week, July 1st to 7th, 1917. The donations amounted, it seems, to over £4000, and this sum, together with the profit on the exhibition and receipts from other sources, made a total of £7275 2*s.* 4*d.* Lord Rhondda, in an introduction to the report, states that an atmosphere of inquiring interest has been created, and suggests that all societies and workers for mothers and children should take advantage of that interest, so that next year the council may be able to focus attention on new points.

THE "CRAIGLEITH HOSPITAL CHRONICLE."

In the Christmas number of the *Craigleith Hospital Chronicle*, which begins a new volume, Sir Ernest Shackleton, R.N., contributes an interesting article entitled "Across the Antarctic in an Open Boat." Notes on the Scottish Navy are continued, and the inspiring story of Some Scottish Regiments, by Dr. J. A. MacDougall, is concluded.

F. T.—If such a case were taken before a county court judge, with the brother as defendant, the chances seem to us to be about equal. Our feeling is that the brother is liable, but that all uncertainty and unpleasantness would have been spared if the medical practitioner had ascertained the pecuniary position from the first. This would have given the brother a chance of limiting his responsibilities or of making some arrangement with the patient.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. B. Moore: The Formation of Nitrites from Nitrates in Aqueous Solution by the Action of Sunlight, and the Assimilation of the Nitrites by Green Leaves in Sunlight.—Mr. J. R. Moir: The Transition from Rostro-carinate Flint Implements to the Tongue-shaped Implements of River-terrace Gravels (communicated by Sir Ray Lankester, K.C.B.).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 10th.

ONTOLOGY (Hon. Secretaries—F. N. Doubleday, J. Howard Mummery): at 7.30 P.M.

Casual Communication:

Mr. W. H. Dolamore: A Case of Gunshot Wound of the Mandible treated with Bruhn's Needles.

Paper:

Major Kazanjain, R.A.M.C.: Osseous Sutures combined with Maxillary Splints for the Immobilisation of Extensive Fractures of the Lower Jaw.

Exhibition:

There will be an Exhibition of Appliances in the Patients' Room behind the West Hall on Monday, Dec. 10th, from 11 A.M. to 7.30 P.M.

Wednesday, Dec. 12th.

OPHTHALMOLOGY (Hon. Secretaries—A. W. Ormond, Leslie Paton): at 8.30 P.M.

Paper:

Lieut.-Colonel Gordon Holmes, C.M.G.: Visual Disturbances from Cerebral Lesions.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—4.30 P.M., Lord Charnwood: Technical Training for Disabled Soldiers and Sailors.

HARVEIAN SOCIETY OF LONDON, at the Library of the St. Mary's Hospital Medical School.

SATURDAY.—5.30 P.M., Discussion on Neurasthenia (opened by Dr. F. W. Mott).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Course of Lectures on the Anatomical and Physiological Principles underlying the Treatment of Injuries to Muscles, Joints, and Bones:—

MONDAY.—5 P.M., Lecture VIII.:—Prof. A. Keith: The Principles underlying the Practice of Modern British Orthopædic Surgeons.

WEDNESDAY.—5 P.M., Lecture IX.:—Prof. A. Keith: The American School of Orthopædic Surgeons.

FRIDAY.—5 P.M., Lecture X.:—Prof. A. Keith: Orthopædic Practice in France and Italy.

The Lectures will be illustrated by specimens from the Army Medical Collection now on exhibition in the Museum and also by specimens from the College Collection.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N. 15

MONDAY.—2.30 P.M., Children's Diseases: Dr. T. R. Whipham. Gynæcological Diseases: Mr. F. L. Provis. Surgical Operations: Mr. E. Gillespie. 3 P.M., Medical In-patients: Dr. R. M. Leslie. 7 P.M., Venereal Clinic: Dr. Kinsella.

TUESDAY.—10 A.M., Surgical Operations: Mr. J. Howell Evans. 2 30 P.M., Medical Out-patients: Dr. A. G. Auld. Surgical Out-patients: Mr. Howell Evans. Nose, Ear, and Throat Diseases: Mr. C. H. Hayton. X Rays: Dr. Metcalfe. 3.30 P.M., Medical In-patients: Dr. A. J. Whiting.

WEDNESDAY.—2.30 P.M., Medical Out-patients: Dr. T. R. Whipham. Diseases of the Skin: The Dermatologist. Eye Diseases: Mr. A. S. Worton. Operations: Nose, Ear, and Throat: Mr. Hayton; 4 P.M., Eyes: Mr. Worton. 5 P.M., Venereal Clinic: Mr. E. Gillespie and Mr. Benians.

THURSDAY.—2.30. P.M., Medical Out-patients, Dr. A. J. Whiting. Surgical: Mr. H. W. Carson. X Rays: Dr. Metcalfe. Gynæcological Operations: Dr. A. E. Giles. 3.30 P.M., Medical In-patients: Dr. R. M. Leslie.

FRIDAY.—2.30 P.M., Surgical Out-patients: Mr. Gillespie. Eye Diseases: Mr. A. S. Worton. 7 P.M., Venereal Clinic: Mr. E. Gillespie and Mr. Benians.

SATURDAY.—2.30 P.M., Surgical Operations Mr. H. W. Carson.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—4 P.M., Dr. C. Kempster: X Rays. Rodent Ulcer and Malignant Diseases.

WEDNESDAY.—5 P.M., Mr. W. Griffith: Skin Diseases in the Army.

THURSDAY.—5 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Erythema and Ul-erythema.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Dec. 5th, 1917.

Date.	Rain-fall.	Solar Radio in Vacuo.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.
Nov. 29	...	65	55	49	48	50	Cloudy
,, 30	...	58	54	49	50	51	Overcast
Dec. 1	...	74	54	48	47	48	Overcast
,, 2	...	60	42	39	36	39	Fine
,, 3	...	56	42	33	31	34	Fine
,, 4	...	44	41	32	31	33	Foggy
,, 5	...	61	43	31	38	41	Overcast

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

TO SUBSCRIBERS IN THE UNITED STATES.

Messrs. Wm. Wood and Co., of New York, are relinquishing their Agency for the supply of THE LANCET in the United States at the end of the present year. The Manager of THE LANCET will be pleased to supply copies direct from the London Office to subscribers in the United States at the strictly prepaid rate of $8 for twelve months. Subscriptions may commence at any time. Drafts and Money Orders should be made payable to the Manager, Mr. CHARLES GOOD, 1, Bedford-street, Strand, London, W.C. 2, England.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

SUBSCRIPTION RATES.

INLAND.

One Year	... £1 10 0
Six Months	... 0 16 0
Three Months	... 0 8 0

COLONIES and ABROAD.

One Year	... £1 12 6
Six Months	... 0 17 6
Three Months	... 0 8 9

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C. 2.

EPSOM COLLEGE

Established in 1855 as a Public School with a Royal Medical Foundation.

***Patron*—HIS MOST GRACIOUS MAJESTY THE KING.**
***President*—THE RIGHT HON. THE EARL OF ROSEBERY, K.G.**
Treasurer—SIR HENRY MORRIS, Bart., F.R.C.S., M.A., M.B.

EPSOM COLLEGE.

Head Master—REV. WALTER JOHN BARTON, M.A., late Scholar of New College, Oxford; formerly Assistant Master at Winchester College.

EPSOM COLLEGE, founded by the late Mr. JOHN PROPERT in 1853, and opened in 1855, is situated fifteen miles from Charing Cross in a most healthy and picturesque position, high up on the Epsom Downs, where the air is very dry and bracing. The College stands in its own estate, consisting of over 80 acres. In front of the main buildings are large ornamental grounds, in which the Chapel forms a conspicuous feature, and there are, beyond, large playing fields of over 26 acres, well adapted for cricket, football, and all other games. There are also several good fives courts.

The closest attention is paid to the sanitary arrangements at the College, which are under the supervision of a permanent Sanitary Inspector. The water is drawn from a well on the premises sunk in the chalk, and analysis shows it to be of the greatest purity.

The College can accommodate 300 Resident Pupils, 50 of whom are the Foundation Scholars. The School is not exclusively for the sons of medical men; boys belonging to other professional and to the higher commercial classes are also educated here. A certain number of Day boys are admitted.

The Lower School, which is preparatory to the College, is a large building, distinct from the College, but within the College grounds. Here, all junior boys from eight years of age, whether ordinary boarders, Foundation Scholars, or Day boys, form a separate department from the main body of the school, both for work and games.

Particular attention is paid to the teaching of Natural Science, for which there are admirably equipped Laboratories and two Lecture Theatres.

Epsom College is on the list of Recognised Institutions approved of by the General Council of Medical Education and Registration of the United Kingdom as places at which medical study may be commenced; and the College is recognised as a "School of Science" by the Committee of the Conjoint Board of the two Royal Colleges of Physicians and Surgeons. Special instruction is given for the First Examination for Medical Degrees of the University of London and for the Matriculation Examination of the same University. Boys are also prepared for the Army, Navy, Civil Service, and for other careers.

Five Medical Scholarships, differing in value, at the Hospital Schools in London, and Nineteen Scholarships, ranging in value from £25 to £60, are awarded under varying conditions—some of them annually, and most of them tenable for several years. Besides these there are "Hugh Vardon" Scholarships of £21 each, Junior Scholarships of £30 each, and Lower School Scholarships of £15 each, awarded annually. School lists, giving full information as to Scholarships, &c., with prospectuses and forms of application, may be obtained on application to the Bursar, at No. 3, The College, Epsom.

ANNUAL FEES.—Sons of medical men, 70 guineas. Those who are not the sons of medical men, 80 guineas. Day Scholars, 25 guineas. Fees are charged for special subjects, as in other schools.

W. DOUGLAS CROSSLEY, Bursar.

ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE.

The Royal Medical Foundation attached to Epsom College gives pensions of £30 each to fifty aged members, or widows of members, of the medical profession in reduced circumstances, and provides gratuitously an education of the highest class at Epsom College, together with clothing, maintenance, and pocket money, for fifty necessitous sons of medical men. It is impossible to maintain this number of Pensioners and Foundation Scholars unless a sum of at least £4500 is obtained by annual contributions.

Did the financial position of the Foundation permit, the Council would be only too glad to increase the total number both of Pensioners and Foundation Scholars, as the applicants very far exceed the number the Foundation is able to help. Many cases of the most heartrending nature, in which immediate aid is sorely needed, have to stand over for a year or two, and some fail altogether to get elected.

Nor must it be overlooked that an increased number of applications for Pensionerships and Foundation Scholarships will be received as a result of the War. Already the Governors have elected as a Foundation Scholar the son of a medical officer in the Royal Navy who was killed in action on board H.M.S. *Good Hope*, and there are on the list of candidates the son of a medical officer in the Royal Army Medical Corps who was lost in the *Royal Edward* when she was torpedoed in August, 1916, and the son of a medical officer who was killed last April whilst in command of a battery in France.

Unfortunately a very large number of annual subscriptions have been withdrawn since the outbreak of War. If the work of the Foundation is to be maintained undiminished, it is essential that subscribers should be secured to make good the losses sustained.

If all friends of the College would take such opportunities as they have of pleading the cause of this Medical Foundation with their well-to-do relatives and friends, the Council would be safeguarded in their efforts to make provision for the wants of those who are forced to plead for help.

The Pensioners and the Foundation Scholars are elected in June by the votes of the Governors.

Donors of Ten Guineas and Collectors of Twenty Guineas are Life Governors, and subscribers of One Guinea annually are Governors during the continuance of their subscriptions. Small contributions are gladly received.

Contributions will be received by the Treasurer, Sir HENRY MORRIS, Bart., 8, Cavendish-square, London, W. 1; by the BRITISH MEDICAL ASSOCIATION, 429, Strand, London, W.C. 2; by BARCLAY'S BANK, Ltd., 19, Fleet-street, London, E.C. 4; and by the SECRETARY, at the office of the College, 37, Soho-square, London, W. 1.

Office: 37, SOHO-SQUARE, LONDON, W. 1,
November 19th, 1917.

J. BERNARD LAMB, Secretary.

LISTERINE

A trustworthy, unirritating solution composed of volatile and non-volatile antiseptics; extensively and satisfactorily employed in dilution up to 25% as a wet dressing for surgical and accidental wounds.

LISTERINE

Suitably diluted, applied by injection, douche or spray, often serves a useful purpose in catarrhs and conditions involving hyper-secretion from mucous surfaces. It is an efficient deodorizer.

LISTERINE

On account of its boric and benzoic acid constituents, forms a suitable lotion in dermatitis following vaccination. In various cutaneous disorders its use allays excessive itching or irritation, and promotes cleanliness while exercising its antiseptic effect.

Descriptive literature on request.

British Agents: S. MAW, SON & SONS, LTD., 7/12, Aldersgate Street, London, E.C. 1.

Alcresta Tablets of Ipecac in Amebic Dysentery and in Endamebic Pyorrhea

The oral administration of the ipecac alkaloids is proving more advantageous than the hypodermatic injection of emetine, especially in the treatment of endamebic carriers and in the prevention of relapses.

UNCOATED AND DISINTEGRATING—CAUSE NO NAUSEA

Each tablet contains the alkaloids (emetine and cephaeline) from ten grains of Ipecac, U. S. P., held in an adsorption compound with hydrated aluminum silicate. The tablets disintegrate but this adsorption compound passes through the acid contents of the stomach and releases the alkaloids only in the alkaline intestinal secretions—thus preventing gastric disturbances.

Ten or twenty tablets, representing one hundred or two hundred grains of ipecac, may be given in a day without vomiting or nausea.

Distributed through the Drug and Dental Trades in bottles containing 40 and 500 tablets. Further information on request.

1867 HAYDEN'S HVC VIBURNUM COMPOUND 1917

In 1867 HAYDEN'S VIRBURNUM COMPOUND was first introduced, and for fifty years it has enjoyed an ever-increasing demand, due to the confidence accorded it by the medical profession for its therapeutic dependability in Gynecological and Obstetrical conditions.

It gains and retains confidence by the results it manifests therapeutically, the only convincing test of the value of a medicinal remedy and upon this basis we invite your consideration.

Accord Hayden's Viburnum Compound a trial in your next Dysmenorrheal patient, and *you will be convinced.* *Dose*: One or two teaspoonfuls three times a day or as required. Administer in three or six teaspoonfuls of hot water.

A supply of the genuine H. V. C., with literature, will be sent you on request.

Battley's Solution of Opium.

Liquor Opii Sedativus

(BATTLEY)

THE OLDEST and still THE BEST Hypnotic and Sedative.

Advantages:

¶ May be given with the greatest safety, being pure and free from harmful matter.

¶ No disagreeable after-effects follow its use.

¶ Never varies in strength.

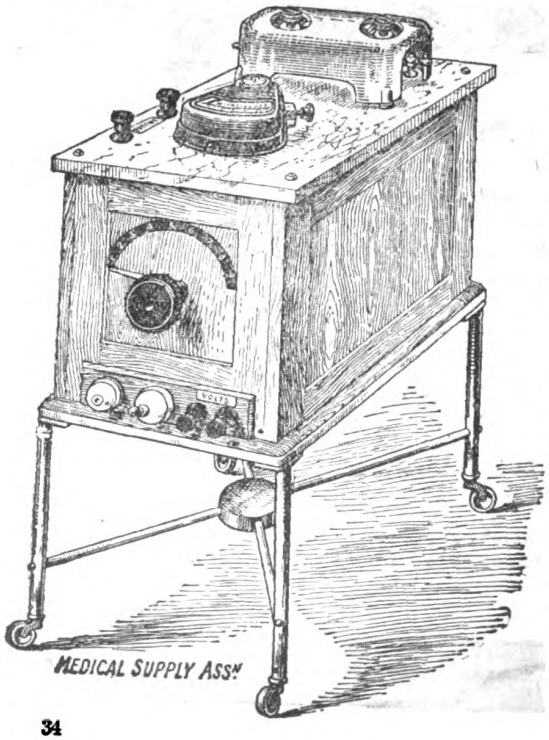
The *Medical Annual* writes:

"**Battley's Solution of Opium** is a common word in the Practitioner's vocabulary. It has gained its reputation by its intrinsic value as a remedy which contains all that is sedative and anodyne in opium without its resinous constituents, which are, therapeutically speaking, impurities."

Strength—Twice that of Tinctura Opii B.P. Usual Dose—5 to 15 minims.

Issued in 2 oz., 4 oz., 8 oz. and 1 lb. bottles.

NOTE.—We do not guarantee our preparations unless in original bottles with the autograph of Richard Battley over each cork and on the label, without which none is genuine.



Sole Manufacturers:

BATTLEY & WATTS, 18 Wellclose Sq., London, E.

"THE HOUSE FOR EVERYTHING ELECTRO-MEDICAL."

THE "GREVILLITE" IMPROVED DIATHERMY APPARATUS

THE BEST For Thermo Penetration Treatment.

It has long been known that the oscillations of ether within the body, when absorbed, develop heat and increase the internal temperature of the body. The electric current also, in passing through the human body, experiences resistance resulting in a transformation of energy which develops the so-called Joule's heat. In all these cases, however, only a slight development of heat, and, therefore, also only a slight rise of temperature, takes place

A much greater development of heat is caused by suppressed electric waves of high frequency. When they pass through the body they create a great increase of temperature. In Diathermic treatment this process is now utilised in various therapeutic applications.

The "GREVILLITE" apparatus is specially designed to create this higher temperature of the body by means of these currents of high frequency.

NO HOSPITAL SHOULD BE WITHOUT THIS VALUABLE TREATMENT.

Price £45:0:0

Owing to prevailing conditions our prices are subject to fluctuation.

A well-known competitor, who has since ordered our apparatus, writes:—

"We have received an order for a Diathermy apparatus and have been asked to supply the best obtainable.

We understand that you manufacture a Diathermy apparatus having a special form of spark gap which works in coal gas.

We shall be glad if you will let us have your quotation." Signed ——

THE BURBERRY

beats every other form of protection, however severe the conditions.

Unlike rubberproofs, or weatherproofs interlined with oiled silk, **THE BURBERRY** is free from the unhealthy heat engendered by airtight fabrics.

Another advantage of **THE BURBERRY** is the permanence of its proofing. Rubber and interlined coats are spoilt by any extreme of cold or heat, but **THE BURBERRY**, owing to the protective agent being ingrained in every thread of the cloth, retains its unrivalled weather-resisting properties throughout the roughest usage in any climate.

BURBERRY SERVICE DRESS

for Doctors and Surgeons, comprises every detail of equipment, including Uniforms and Greatcoats, made from hard-wearing cloth, proofed by Burberry processes.

READY FOR IMMEDIATE WEAR or made to measure in from 2 to 4 days.

BLENOSAN
CAPSULES

As a routine
treatment for

GENITO-URINARY CONDITIONS.

BLENOSAN is a mixture of the finest East India Santal Oil with a specially prepared fluid extract of Kava-Kava. It is presented in the form of accurately-measured Capsules, and affords an ideal medicament for the treatment of all inflammatory conditions of the urethra.

BLENOSAN is an improvement upon the ordinary Santal, and the full proportion of the alpha resin of Kava-Kava ensures all the anæsthetic and diuretic properties of the root in a standardised and dependable form.

BLENOSAN CAPSULES consequently are indicated in all pathological conditions which affect the genito-urinary system, including acute Cystitis, Vaginitis, and Leucorrhœa, and where intense hyperæmia and swelling of the mucous membrane give rise to a diminution of the urinary canal.

BLENOSAN CAPSULES are well adapted for the continuous and systematic treatment of such cases, and are being used with excellent results by many of the most experienced and successful Physicians.

BLENOSAN CAPSULES can be prescribed for a course of treatment extending over two or three weeks.

Point 1.

The Safety of Kerocain.

NOT in the domain of local analgesia a one, but by comparison wi h general anaesthetic agents also, is the Safety of Kerocain pre-eminent.

Whether employed alone or as an adjunct to anoci-association technique the use of Kerocain is unattended by the dangers that are practically inseparable from other anaesthetic agents.

Kerocain is non-toxic and non-irritant, has no effect on the action of the heart, nor on the central nervous system, and may be safely combined with adrenalin. Kerocain-adrenalin anaesthesia may in fact be employed with confidence even in those conditions where chloroform and adrenalin is a notoriously unsafe combination.

Kerocain is chemically, physiologically, and therapeutically identical with German novocain, and is manufactured and standardised in our laboratories at Bardsley Vale, under licence from the British Board of Trade, and is tested under arrangements approved by the Board.

A free copy of our new illustrated booklet, dealing with "The Theory and Practice of Local Anaesthesia and Anoci-association," will be sent to any Surgeon on request

The Winter Tonic

WITH winter bearing down upon us, the demand for Hall's Wine becomes more urgent every day. Acting on medical advice, sufferers from nerve shock, depression, insomnia, anæmia, and weakness are fortifying their systems with Hall's Wine to withstand the bitter weather.

For over a quarter of a century Hall's Wine has been prescribed by doctors with beneficial results. From medical men and patients alike we are constantly receiving reliable testimony as to the speedy and lasting benefits following a course of Hall's Wine.

The past experience of the faculty justifies the recommendation of Hall's Wine wherever a tonic restorative is required.

Hall's Wine

THE SUPREME RESTORATIVE

Sold by all Wine Merchants, and Grocers and Chemists with Wine Licences.

To the Professional Men of Britain—

BURN LESS FUEL!

We are short of all kinds of fuel

—not merely of coal, but of oil and gas also.

That is a fact which you must take to heart.

The Government have asked you to economise in coal consumption and to use gas rather than coal—but they have also asked you to

be economical in your use of gas

for lighting, heating, water-heating, and cooking.

The supply of gas is temporarily limited. It is not possible to enlarge gas works to any extent during the war, and the output of many existing works is restricted by shortage of labour and materials; while—on account of the increased demand for gas for munition works, and of the unprecedented growth in its use for industrial and domestic purposes (caused partly by the loyal response to the Government appeal to use gas instead of coal)—the supply of

gas will run short this winter

for War Needs—which must come before Private Needs—unless everyone exercises the strictest economy in its use.

The British Commercial Gas Association, 47, Victoria Street, Westminster, S.W.1.

MATLOCK SANATORIUM

Situated on the edge of the mountain limestone area of Derbyshire, over 700 feet above sea-level. The buildings face south and command beautiful views, while on the north and east they are sheltered by lofty hills. The surrounding country is well known for its great beauty and interest. The climate is dry and bracing. The buildings are lighted by electricity and heated by radiators.

Treatment is carried out on modern lines, all special methods being available in suitable cases. A new X-ray apparatus has been installed, and there is a complete equipment for the carrying out of up-to-date methods in all Tubercular and other Pulmonary cases.

For particulars apply to FREDERICK KINCAID, M.R.C.S., L.R.C.P., Medical Superintendent, Matlock Sanatorium, Matlock, Derbyshire. Telephone and Telegraph: SANATORIUM, MATLOCK 22.

VALE OF CLWYD SANATORIUM

This Sanatorium (opened 1901) is established for the Treatment of Tuberculosis as carried out by Dr. OTTO WALTHER of Nordrach. It is situated in the midst of a large area of park-land, at a height of 450 feet above the sea-level, on the western slopes of mountains rising to over 1800 feet, which protect it from North and East winds and provide many miles of carefully graduated uphill walks—similar in character and extent to those at Nordrach.

Small rainfall. Porous subsoil. Large amount of sunshine. Electric Lighting and Hot Water Radiators in each room.
The physician himself was a patient at Nordrach.
For particulars, apply to GEORGE A. CRACE-CALVERT, M.B., &c., Llanbedr Hall, Ruthin, North Wales.

"Science is, I believe, nothing but trained and organized common-sense, differing from the latter only as a veteran may differ from a raw recruit: and its methods differ from those of common-sense only so far as the Guardsman's cut and thrust differ from the manner in which a savage wields his club."

Professor Huxley.

The Basis of Science

BOOTS PURE DRUG COMPANY LIMITED wish to draw the attention of the medical profession to the following seven scientific preparations. Practitioners who endeavour to keep abreast of the times will find these modern antiseptics of superlative value in general practice.

CHLORAMINE-T

(p-toluene-sodium-sulphochloramide).

Dakin's ideal antiseptic, of wide applicability in medicine and surgery.

In bottles of 1oz., **1/2**; 4oz., **3/6**; 1lb., **12/6**

CHLORAMINE-T GAUZE

In two strengths, containing approximately 5% and 35% Chloramine-T. (5% supplied unless otherwise specified). This should be fixed dry and subsequently moistened, if necessary, when in position.

In sealed packages only, price **1/-** per package.

PROFLAVINE

(3·6 diamino-acridine-sulphate).

The improved Flavine derivative.

Equal in antiseptic powers to ***Acriflavine,*** and in important respects superior, being markedly less toxic and less irritating. Proflavine, being less costly to manufacture, can be sold at a substantially lower price than Acriflavine.

5 gram bottle, **1/4**; 20 gram bottle, **5/-**

TABLETS OF CHLORAMINE-T

One tablet dissolved in two ounces of water makes a one per cent. solution.

Bottles of 50, 8·75 grain tablets, **2/-**
" " 100, " " " **3/9**

One tablet dissolved in ten ounces of water makes a one per cent. solution.

Bottles of 12, 43·75 grain tablets, **1/10**

CHLORAMINE-T CREAM

Containing approximately one per cent. Chloramine-T. Described and investigated under the name of Chloramine Paste by Vincent Daufresne, Carrel, Hartmann and others, in the *Journal of Experimental Medicine*, 1917.

In Pots. Trial size, **9d.**; large size, **2/6.**

TABLETS OF PROFLAVINE

(with sodium chloride).

One tablet dissolved in four fluid ounces sterile water makes 1:1000 Proflavine in normal saline.

Bottles of 100 tablets, **3/6**

HALAZONE TABLETS.

DAKIN'S NEW WATER DISINFECTANT.
Vide B.M.J., May, 1917.

The action of Halazone is positive, and may be relied upon for crudest waters. Each tablet is sufficient to sterilize one quart of contaminated water, but in cases of extreme contamination a second tablet may be necessary. Halazone is invaluable for those on active service overseas, more particularly in hot climates.

Bottles of 100 tablets, **6d.**

Supplies are available for prescription service on application through any of the branches of BOOTS THE CHEMISTS.

Boots Pure Drug Company Limited

MANUFACTURING CHEMISTS AND MAKERS OF FINE CHEMICALS.

Head Offices: Station Street, Nottingham. JESSE BOOT, Managing Director.

PRINTED and PUBLISHED by the PROPRIETORS, WARLEY AND SON (1912), LTD., at No. 423 Strand, and Nos. 1 and 2, Bedford-street, adjoining, in the County of London.—Saturday, Dec. 8th, 1917.

SAUNDERS' BOOKS

McKenzie on Exercise — SECOND EDITION

For this new edition the entire work has been subjected to a most searching revision. New matter to the extent of *175 pages* has been added and *132 additional illustrations* have been included. These additions make the work express the very latest advances both in the developmental exercises and physical training of the school, gymnasium, field and playground, and the application of systematic exercises and athletics to the correction of deformities and certain functional derangements.

Octavo of 585 pages, with 478 illustrations. By R. TAIT MCKENZIE, M.D., Professor of Physical Education, and Director of the Department, University of Pennsylvania. Cloth, 18s. net.

Vecki's Sexual Impotence — FIFTH EDITION

This work is a pioneer in this field. Five editions testify to its value. The whole subject is covered—anatomy, physiology of the sexual act, etiology of impotence, various forms, diagnosis, prognosis, prophylaxis, and treatment (psychic, hygienic, drug, hydrotherapy, electrotherapy, local massage, gymnastics, suggestion, psycho-analysis, organotherapy).

12mo of 400 pages. By VICTOR G. VECKI, M.D., Consulting Genito-Urinary Surgeon to the Mount Zion Hospital, San Francisco. Cloth, 10s. 6d. net.

Stevens' Practice of Medicine — TENTH EDITION

In preparing this new edition Dr. Stevens has carefully revised the text throughout. He has entirely rewritten some of the chapters; added a number of new ones, and there is scarcely one he has not enlarged or otherwise changed by the addition of new matter.

12mo of 629 pages, illustrated. By A. A. STEVENS, M.D., Lecturer on Medicine, University of Pennsylvania. Cloth, 12s. 6d. net.

Hill and Gerstley's Infant Feeding — JUST READY

In these clinics you are given the full details of the *Boston method* of infant feeding as developed by Dr. Rotch, and of the *Chicago method*. You are given the theory, use in both normal and abnormal cases, exact quantities and percentages, and concrete clinical examples. The book is almost equivalent to a postgraduate course in infant feeding.

12mo of 350 pages, illustrated. *Boston Methods* by LEWIS WEBB HILL, M.D., Alumni Assistant in Pediatrics, Harvard Medical School. *Chicago Methods* by JESSE R. GERSTLEY, M.D., Clinical Assistant in Pediatrics, Northwestern University Medical School, Chicago. Cloth, 12s. 6d. net.

Stelwagon on the Skin — EIGHTH EDITION

There are two features in Dr Stelwagon's work that stand out above all others: The special emphasis given *diagnosis* and *treatment*; and the *wealth of illustrations*. These latter teach you diagnosis as no description can. Over 75 pages are devoted to *syphilis* alone. *Pellagra*, tropical affections, *hookworm disease*—all those diseases being so widely discussed to-day are included.

Octavo of 1309 pages, 356 text-cuts, 33 plates. By HENRY W. STELWAGON, M.D., Professor of Dermatology in Jefferson Medical College, Philadelphia. Cloth, 28s. net.

Ruhräh's Diseases of Children — FOURTH EDITION

This new edition contains articles on pellagra, use of soy bean, drug eruptions, Binet-Simon test for mentality. A number of valuable prescriptions are included and the references to pediatric literature form an important feature. It is a concise and complete work for the busy practitioner and pediatrist. There are 175 instructive illustrations.

12mo of 552 pages, illustrated. By JOHN RUHRÄH, M.D., Professor of Diseases of Children, College of Physicians and Surgeons, Baltimore. Cloth, 12s. 6d. net.

Books sent, Carriage Paid, on Receipt of Price.

W. B. SAUNDERS COMPANY, 9, Henrietta Street, London, W.C. 2.

Now Ready. THIRD EDITION. Fully Revised and Enlarged. Large 8vo. 39 Coloured Plates and over 300 Illustrations in the text, and a fully detailed General Index, containing upwards of 45,000 References. **£2 2 0 net.**

PHILIP TURNER, M.B., M.S.
W. HALE WHITE, M.D., F.R.C.P.

This work aims at being of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain. It covers the whole ground of Medicine, Surgery, Gynæcology, Ophthalmology, Dermatology, and Neurology.

It is a work upon differential diagnosis in that it discusses the methods of distinguishing between the various diseases in which each individual symptom may be observed. The body of the book deals with *Symptoms*, while the General Index, containing some 45,000 references, gathers these together under the various *Diseases* in which they occur

The second edition was exhausted within nine months of issue, and a third is now issued.

"The new edition is an improvement in many ways on the old, and has been re-cast on ampler lines, with a large number of new illustrations and coloured plates. Having read most of the articles in the book, we have no hesitation in saying that it should be in the hands of all practitioners and senior students. . . . The publisher is to be congratulated upon the printing of the book and its illustrations, perhaps most of all upon the excellence of the many coloured plates; they could not be better, and do great credit to British colour printing."—BRIT. MED. JOUR.

"The first edition of this stately volume has been exhausted within three years. ..... The editor has added new articles, revised old ones, and nearly doubled the number of illustrations. These are not only excellently reproduced, but deal with real difficulties in diagnosis"—LANCET.

"Beyond question a *tour de force*, and reflects the highest credit upon all concerned in its production. The most remarkable feature in the book is its full index ..... an essential part of the scheme ..... will be found a friend in need at all times. ..... We are extremely glad as well to have it made abundantly evident that the finest productions from overseas can be left far behind on every point by those brought forth in this country."—PRACT.

"The volume is a notable contribution to modern medicine ..... an immense amount of valuable information. ..... The illustrations are remarkably good, especially the coloured ones, which in other books often are remarkably bad."—THERAP. GAZETTE.

"It is not difficult to understand why this work has been twice reprinted since 1912, and that a second edition has now been called for. It satisfactorily meets a want which every practitioner experiences almost daily."—EDIN. MED. JOUR.

Bristol: JOHN WRIGHT & SONS, Ltd. London: SIMPKIN & CO., Ltd.

NOW READY. THIRD EDITION

HYGIENE AND PUBLIC HEALTH

WITH SPECIAL REFERENCE TO THE TROPICS.

By **B. N. GHOSH,** F.R.F.P.S (Glasg.),
Fellow of the Royal Society of Medicine; and

SECOND EDITION. 566 Illustrations, 10 in Colour. 21s. net.

STARLING'S PRINCIPLES OF PHYSIOLOGY

By **ERNEST H. STARLING**, M.D., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London.

"The book has a special value for the medical practitioner, as well as for the student who has to face examinations in physiology. ..... There is nothing of the cut-and-dried formalism so common in scientific text-books about this volume, which is characterised by a broad outlook on the problems of physiology and an unusual readiness to fall back on other kindred sciences in the endeavour to bring these problems towards a satisfactory solution. The book should be widely read by those for whom it is written, and we wish it all success."—BRITISH MEDICAL JOURNAL.

With 74 Illustrations, some in Colours.

MEDICAL DIAGNOSIS

15s. net.

By **ARTHUR LATHAM**, M.D. Oxon., F.R.C.P. Lond., Physician and Lecturer on Medicine, St. George's Hospital; and **J. A. TORRENS**, M.B., B.S. Lond., M.R.C.P. Lond., Assistant Physician, St. George's Hospital

"A valuable handbook conveniently arranged, efficiently illustrated." EDINBURGH MEDICAL JOURNAL.

London: J. & A. CHURCHILL, 7, Great Marlborough Street, W. 1.

MILITARY MEDICAL MANUALS

Under the general Editorship of DIRECTOR-GENERAL

Sir ALFRED KEOGH, G.C.B., LL.D., M.D., F.R.C.P., &c.

This Series covers the whole field of War Medicine and Surgery, and its predominant note is the exhaustive, practical, & up-to-date manner in which it handles the new knowledge obtained at the Front.

Each volume has been written by a leading authority as a result, in most cases, of extensive first-hand experience in the field.

Volumes Published this Week.

DYSENTERIES, CHOLERA, AND EXANTHEMATIC TYPHUS

By H. VINCENT, *Medical Inspector of the Army; Member of the Academy of Medicine;* and L. MURATET, *Director of Studies in the Faculty of Medicine, Bordeaux*

Edited by Col. ANDREW BALFOUR and Capt. G. C. LOW. Price 6s. net. Postage 5d.

THE PSYCHONEUROSES OF WAR

By Dr. G. ROUSSY, *Assistant Professor in the Faculty of Medicine, Paris;* and JEAN LHERMITTE, *Sometime Laboratory Director in the Faculty of Medicine, Paris.*

Edited by Col. W. ALDREN TURNER, M.D., R.A.M.C. With 13 full-page Plates. Price 6s. net. Postage 5d.

SYPHILIS AND THE ARMY

By G. THIBIERGE, *Physician of the Hôpital Saint-Louis.*

Edited by C. F. MARSHALL, F.R.C.S. Price 6s. net. Postage 5d.

TYPHOID FEVERS & PARATYPHOID FEVERS

(Symptomatology, Etiology, and Prophylaxis)

By H. VINCENT, *Medical Inspector of the Army; Member of the Academy of Medicine;* and L. MURATET, *Superintendent of Laboratories at the Faculty of Medicine at Bordeaux.*

Translated from Second Edition and Edited by J. D. ROLLESTON, M.D. Price 6s. net. Postage 5d.

THE AFTER-EFFECTS OF WOUNDS OF THE BONES AND JOINTS

By AUG. BROCA, *Professor of Topographical Anatomy in the Faculty of Medicine, Paris.*

Edited by R. C. ELMSLIE, M.S., F.R.C.S., Capt., R.A.M.C., &c. With 112 original Illustrations. Price 6s. net. Postage 5d.

HYSTERIA OR PITHIATISM, AND REFLEX NERVOUS DISORDERS

By J. BABINSKI, *Member of the French Academy of Medicine;* and J. FROMENT, *Assistant Professor and Physician to the Hospitals of Lyons.*

Edited by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Capt., R.A.M.C. With Illustrations and 8 full-page Plates. Price 6s. net. Postage 5d.

THE TREATMENT OF INFECTED WOUNDS

By A. CARREL and G. DEHELLY.

With Introduction by Surg.-Gen. SIR ANTHONY A. BOWLBY. With numerous Illus. Price 5s. net. Postage 5d.

Volumes Ready in January.

THE FRACTURES OF THE ORBIT AND INJURIES OF THE EYE IN WAR

By FELIX LAGRANGE, *Professor in the Faculty of Medicine, Bordeaux.*

Edited by J. HERBERT PARSONS, D.Sc., F.R.C.S., Temp. Capt., R.A.M.C. With 77 original Illustrations and 6 full-page Plates. Price 6s. net. Postage 5d.

THE CLINICAL FORMS OF NERVE LESIONS

By Mme. ATHANASSIO BENISTY, *House Physician of the Hospitals of Paris (Salpêtrière).*

With a Preface by Prof. PIERRE MARIE. Edited with a Preface by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Capt., R.A.M.C.T., &c. With 81 original Illustrations in text and 7 full-page Plates. Price 6s. net. Postage 5d.

THE TREATMENT AND REPAIR OF NERVE LESIONS

By Mme. ATHANASSIO BENISTY, *House Physician of the Hospitals of Paris.*

With a Preface by Prof. PIERRE MARIE, Members of the French Academy of Medicine. Edited by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Captain, R.A.M.C.T., &c. With 62 Illustrations in the text and 4 full-page Plates. Price 6s. net. Postage 5d.

FRACTURES OF THE LOWER JAW

By L. IMBERT, *National Correspondent of the Société de Chirurgie;* and PIERRE REAL, *Dentist to the Hospitals of Paris.*

With a Preface by Medical Inspector-General FEVRIER. Edited by J. F. COLYER, F.R.C.S., L.R.C.P., &c. With 97 Illustrations and 5 full-page Plates. Price 6s. net. Postage 5d.

THE TREATMENT OF FRACTURES

By R. LERICHE, *Assistant Professor of the Faculty of Medicine, Lyons.*

Edited by F. F. BURGHARD, M.S., F.R.C.S. In Two Volumes.

Vol. I.—Fractures Involving Joints.

With 97 Illustrations from original and specially prepared drawings. Price 6s. net. Postage 5d. extra.

Vol. II.—Fractures of the Shaft.

With 156 Illustrations from original and specially prepared drawings. Price 6s. net. Postage 5d.

ARTIFICIAL LIMBS

By A. BROCA, *Professor in the Faculty of Medicine, Paris;* and Dr. DUCROQUET, *Surgeon at the Rothschild Hospital.*

Edited by R. C. ELMSLIE, M.S., F.R.C.S., Capt., R.A.M.C., &c. With 210 original Illustrations. Price 6s. net. Postage 5d.

A DESCRIPTIVE LIST, containing full particulars of the Volumes now issued and of a large number of Volumes almost ready for publication, will be sent post free upon application.

CATALOGUE of SECONDHAND SURGICAL INSTRUMENTS, OSTEOLOGY, MICROSCOPES, POST FREE.

Students' Half Sets of Osteology. Articulated Skeletons and Disarticulated Skulls.

Secondhand Surgical Instruments, Osteology and Microscopes bought, sold and exchanged.

MILLIKIN & LAWLEY, 165, STRAND, LONDON, W.C. 2. Telephone: City 1708.

ASTHMA,

CHRONIC BRONCHITIS, BRONCHITIS, ASTHMA, HAY FEVER, and INFLUENZA.

This remedy is made by passing thick bibulous paper through a Solution of Nitrate of Potash, Chlorate of Potash, and other Chemicals.

DIRECTIONS.—Fold and place one or two pieces of paper on a dish and light the top as illustrated. A dense fume will then arise and gradually fill the room; and after inhaling it for a few minutes the air tubes will be cleared of mucus, the difficult respiration will cease, and the patient will fall into a sound and refreshing sleep. The outer air must be excluded by keeping the windows, doors, and chimney closed. The paper may be burned in the day as well as at night if necessary.

Price 2s. 9d., 4s. 6d., and 11s. per box.

Dr. Thorowgood, Physician of the City of London Hospital for Diseases of the Chest, in his "Notes on Asthma," page 62, says:—"The Ozone Paper prepared by Mr. Huggins contains nitrate of potash, chlorate of potash, and iodide of potassium, and of its efficacy I have had abundant evidence." Dr. Woodward, Worcester:—"Your Ozone Papers have given me more permanent benefit than any other remedy I have tried I have also found the same with regard to my Asthmatic patients."

Usual discount to the Profession and Trade.

Prepared by

R. HUGGINS & CO., Chemists, 199, STRAND, LONDON.

The NORWICH

CRÊPE ✚ BANDAGE

SUPERIOR ENGLISH MANUFACTURE

Extremely elastic, but contains no rubber.

FAST WOVEN EDGES.

Invaluable for all binding purposes. Entirely displaces bandages of rubber and elastic web. Considerably more durable, although less than one-third the cost of rubber or elastic web. Varicose veins and other ailments requiring the use of bandages usually demand *warmth* as well as support. The Norwich Crêpe Bandages, containing wool, provide this warmth and do not absorb grease. May be thoroughly cleansed by the use of *hot* (not boiling) soapy water, with the addition of a little ammonia or soda. Healthy and comfortable to wear, giving the necessary firmness, yet yielding to every movement. Self-clinging and self-adjusting.

"It's the greatest comfort in the world for every case of Varicose Veins."

THE BANDAGE THAT CAN BE STERILIZED.

IMPORTANT.—The edges will not fray out nor ravel.

Made and supplied to the leading wholesale houses, neatly wrapped in labelled packages. Inexpensive and high in quality; universally commended by the medical and nursing professions. Send for prices and samples to the Sole Manufacturers:

THE NORWICH CRAPE CO. (1856), LTD.,
St. Augustine's Silk Mills, Norwich, Eng.

London buyers can obtain samples and prices from Mr. T. Eastaway, London representative, 7, Wool Exchange, E.C.2

Prescribed by the Medical Profession for 35 years.

The LANCET (London, Eng.) says: "So many worthless articles of this kind have been sold that great care is required in choosing those upon which reliance can be placed. Mr. Benger's care has therefore been well spent."

Benger's Food

has been described as—

'The physician's dietetic sheet Anchor.

IT is not one of the "made in a moment" variety of foods. On the contrary, its preparation takes a little time, and, although simple, requires a little care.

This is because the amylolytic and tryptic ferments scientifically combined in BENGER'S FOOD act upon the fresh milk with which it is prepared, and also upon the food itself. As a result—

Fresh new milk and BENGER'S FOOD combine to form a delicious FOOD CREAM.

so light as to be available for invalids prostrate with illness, and so rich in nutrition as to contain all that is necessary to sustain life in a vigorous adult.

It is no platitude, therefore, to describe BENGER'S as "different from any other food obtainable."

BENGER'S Food

for INFANTS, INVALIDS, AND THE AGED,

is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

BENGER'S FOOD Ltd.,——Otter Works, MANCHESTER, Eng.

Branch Offices

STOVAINE

THE LEAST TOXIC OF LOCAL ANÆSTHETICS

USED IN THE SAME WAY AND AS EFFICACIOUS AS COCAINE

Does not create a habit and does not give rise to headaches, nausea, vertigo or syncope. :: :: *Literature on demand.*

NO HOME OFFICE LICENSE REQUIRED

Cheaper than Novocain and Benzocain and obtainable promptly in practically unlimited quantities from the manufacturers:

LES ETABLISSEMENTS POULENC FRERES

92, RUE VIEILLE DU TEMPLE, PARIS.

GOUT & RHEUMATISM

¶ BETUL-OL rapidly penetrates the skin, producing anodyne effects and local antiseptic action at the seat of inflammatory rheumatic, gouty, neuralgic, or sciatic pain.

¶ BETUL-OL is a solution of menthol and chloral in methyl salicylate, soluble in all proportions of ether, alcohol, chloroform, or oils. After application of BETUL-OL a wet piece of tissue paper produces physico-chemical action, hyperemia and rapid relief of local pain.

Original Bottles of 2-oz., 4-oz., 8-oz., 16-oz.

¶ COLCHI-SAL promotes normal metabolism and removes the underlying cause in rheumatic and gouty diathesis.

¶ Each capsule of 20 centigrams contains: 1/4 milligram (1.250 gr.) of colchicine, 1/8 milligram active principle of canabis indica dissolved in methyl salicylate *(from betula lenta)* with appropriate adjuvants to ensure toleration by the stomach.

Original Bottles of 50 and 100 Capsules.

Free samples from

Croydon, London.

A few words to the Profession about

Celesco

The New Food Beverage

WE wish to bring to the notice of the Medical Profession the new food beverage—**CELESCO.**

CELESCO possesses a particularly delightful flavour and is practically free from tannin. Its highly stimulating properties are largely derived from theobromine, the essential alkaloid of cocoa. Medical men will find this nourishing food beverage of great value in cases of digestive trouble.

CELESCO costs substantially less than tea, coffee, or cocoa, and when infused it makes an invigorating and very refreshing drink.

Sold by Chemists, Grocers, and Stores.
If unobtainable, apply direct to Celesco Department.

A Great Advance
in a
BRITISH INDUSTRY

"SAPON" SOAPS

As a result of sixteen years' strenuous work in chemical research and its practical application, the foundation has been securely laid for the rapid development of a great British industry.

"SAPON" SOAP—a British invention, developed with British Capital—is the first great advance in the chemistry of Soap since that article was first manufactured. Patents have been obtained for the invention in almost every country of the world, and it cannot fail to be as great a commercial success as Margarine has proved to be.

Margarine was laughed at by scientific men in its initial stages, and the public, through powerful vested interests, were made sceptical of its value as a food. Even Acts of Parliament were obtained to try and prevent its progress, but the exigencies of the time, since war broke out, have swept away nine-tenths of the opposition, and to-day margarine is being consumed in rapidly increasing quantities. Thousands of tons are made and sold in this country weekly. No maker of Margarine claims that it is better than Butter as a food, but the makers of "Sapon" Soap can and do claim that "Sapon" is better than any Soaps hitherto in use.

"SAPON" SOAP has had to face very strong opposition from Soap Chemists and others, but it is now frankly acknowledged by the best chemical authorities in this country that "Sapon" Soaps have twice the cleansing properties of Fat Soaps, and C. F. Townsend, F.C.S., in a recent article contributed by him to *Chambers's Journal* for September, 1917, shows that in hard water (such as London water) over £1,000,000 worth of valuable Fats go down the drains of London every year without having been of the slightest service to anyone. Therefore, it requires no great stretch of imagination to anticipate the time when the public will wonder why Oils and Fat, suitable for human food, should be wasted in the manufacture of Soap, when materials (by-products) that are unsuitable for human food can be made into Soap containing greater cleansing properties than those of Fat Soaps; and when the public realises what the scum (Lime Soap) deposited on wash-hand basins, sponges, and face cloths, &c., means when applied to the human skin, there is bound to be a great reaction and rejection of Soap produced from boiled Fat and Oils and expensive and injurious Scents, and a corresponding demand for health-giving and economic Soap produced by the "Sapon" process.

The latest addition to the various Soaps manufactured under this process, viz., Russian Tar Soap, has cleansing, disinfectant, and skin-healing properties such as have not hitherto been available in any Soap.

Further information, if desired, can be obtained on application to the Secretary.

'SEDOBROL'

TRADE-ROCHE-MARK

THE need for a reliable preparation which can be prescribed as a diet rather than a drug, makes itself felt especially in cases of

NEURASTHENIA, HYSTERIA, EPILEPSY, AND MENTAL DISORDERS.

Where continuous bromide treatment is necessary, the daily use of 'Sedobrol' combined with the withdrawal or limitation of salt, has proved an excellent routine treatment. (Ulrich).

A Cup of Hot 'SEDOBROL'

has the flavour of a savoury bouillon, and is made in a few moments.

'Sedobrol' Roche contains 17 grs. (1·1 gm.) of Sod. Bromide in combination with fat and spicy extractives of vegetable proteins.

'Sedobrol' Roche is PALATABLE, ASSIMILABLE, and SAFE.

DOSE One or more tablets at bedtime or whenever necessary.

In tins of 10, 30, 60 & 100 tablets, of all Chemists.

Descriptive literature and specimen from

Body Nutrition.

Cod-Liver Oil Emulsion, 33% (P., D. & Co.) contains a definite, stated, amount of the finest cod-liver oil, so presented as to ensure assimilation without gastric disturbance.

Special precautions are taken during its manufacture to preclude oxidation of the oil, since oxidation causes diminution in therapeutic value, and produces the rank flavour which makes some cod-liver oil preparations so objectionable.

The flavour of the "P., D. & Co." Cod-Liver Oil Emulsion is so agreeable that the most sensitive patients can take it regularly, whilst the amount of oil contained is such as can readily be assimilated without risk of provoking nausea; hence it is calculated to produce the best effects.

In addition to the nutritive value of the oil, the "P., D. & Co." 33% Emulsion provides the tonic-alterative action of the hypophosphites.

The "P., D. & Co." 33% Emulsion is obtainable of all chemists—in bottles of 5, 8 and 16 ozs.

A thoroughly reliable preparation is ensured to the patient when the prescriber writes:—

"Emuls. Ol. Morrhuae, 33%, P., D. & Co."

A sample and further particulars will be sent on request.

PARKE, DAVIS & CO., LONDON.

In the Period of Convalescence.

Medical men who by clinical experience are already convinced of the tonic and reconstructive merits of Angier's Emulsion, should put this pleasant and simple remedy to the test in the convalescent period.

ANGIER'S EMULSION

PETROLEUM WITH HYPOPHOSPHITES

In this remedy you have an agent that will heal intestinal lesions, correct perverted metabolic action, promote absorption, assimilation, nutrition, and restore tone to all the digestive functions. The creation of appetite and the return of normal digestion is quickly brought about by its regular use.

An absolutely perfect Emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Moreover, its good effects are accomplished in a safe and natural manner without entailing extra work upon the weak or overburdened system.

(LYSOL BRITISH)

LYCRESOL

A Standardised Disinfectant

Lycresol is a well-tried antiseptic in concentrated form for the use of doctors and nurses. It contains a high percentage of cresol, and is superior as a general disinfectant and deodoriser to carbolic acid.

Lycresol forms a saponaceous solution with a detergent action which removes mucous secretions, etc., with adherent germs.

A Measuring Cup with each bottle.

Price — 4 oz. 7½d.; 8 oz. 1/-; 16 oz. 1/9; 32 oz. 3/-; 1 gall. tins 12/-

Free Sample to Medical Profession.

A powerful urinary antiseptic.

CYSTOFORMIN is indicated in all infected conditions of the urinary tract; in phosphaturia where it diminishes the amount of deposition, in cystitis, and gonorrhoea. It forms a useful prophylactic for use where instrumental interference with the bladder becomes necessary, and is of great value before and after operation in this region.

The primary action of Cystoformin is that of a powerful urinary antiseptic, and in this field, its range of usefulness is very wide, embracing practically every infected condition of the bladder or urinary tract.

Cystoformin

Reg. Trade Mark

Composition: — Hexamine with Sodium Acetate representing 40 per cent. of its weight of the former. In 17 gr. tablets.

An average dose is one tablet three times daily dissolved in plain or aerated water.

Sold in tubes containing about 20 tablets, 1/6 each.

Free Sample to Medical Profession.

Awarded Gold Medal at the International Congress of Medicine, London, 1913.

Vitafer

The All-British Tonic Food

In sealed tins, price 1/6 and 2/6 of all Chemists; larger sizes 4/6 and 7/6

Vitafer, introduced after much research before the outbreak of War, as superior to any British or foreign product of the same class, now holds the foremost place amongst Tonic Foods. The manufacturers are confident that British Medical Men will appreciate the opportunity of supporting and prescribing Vitafer, which from its inception, has been entirely free from enemy taint.

A doctor's sample will be sent free and post paid to any Medical Practitioners on request.

Byno Cascada

(Trade Marks)

The Ideal Tonic Laxative and Nutrient Digestive.

"BYNO CASCADA" presents the stimulating tonic laxative principles of the finest Cascara Sagrada and Rhamnus Frangula incorporated in "Bynin" pure active liquid malt.

The gentle, yet persistent, tonic effect of Cascara on the intestinal muscle, reinforced by the influence of "Bynin," in promoting the digestion and assimilation of food, renders "Byno Cascada" the ideal prescription to ensure normal bowel activity.

Equally valuable in childhood, in pregnancy, for nursing mothers, and in old age, "Byno Cascada" is preferred in scientific treatment.

Issued in Bottles at

3/- and 5 6.

Descriptive Pamphlet and Sample Free to Medical Men.

'Byno' Hypophosphites
TRADE MARK

"One of the most popular tonics of the day."
British Medical Journal.

"Byno" Hypophosphites combines the nutritive and digestive principles of the finest Malt Extract with Hypophosphites, a powerful tonic nerve food. It is much superior to the official syrup, and in many years' clinical experience has given most gratifying results. "Byno" Hypophosphites may be taken when ordinary tonics cannot be tolerated.

As a General Tonic

"Byno" Hypophosphites is unrivalled; it contains a variety of principles which each have their particular therapeutic value.

Tuberculosis

In the wasting of Tubercular Cachexia it tends to reduce the temperature, improve the appetite, increase the weight, and rehabilitate the nervous system.

Typhoid Fever

In the slow convalescence from Typhoid Fever it is an easily absorbed and highly nutritious tonic food. "Byno" Hypophosphites helps the enfeebled digestion, decreases the anæmia, and improves the general tone of the nervous system. Owing to the presence of 'Bynin,' it is not constipating in its action.

FORMULA:

Calcium Hypophosphite	2 gr.
Potassium ,,	2 ,,
Sodium ,,	2 ,,
Iron ,,	¼ ,,
Manganese ,,	¼ ,,
Cinchona Alkaloids	1½ ,,
Nux Vomica ,, *Equal to Strychnine*	⅛ ,,
Bynin" Liquid Malt	1 oz.

Influenza and Malaria

For those debilitated by Influenza, Malarial and Tropical Diseases, it has proved itself an invaluable restorative and reconstructive.

In Old Age

For the Aged and Infirm there is no preparation so acceptable and so readily assimilated. It stimulates a flagging heart and is not only a tonic but a food.

Brain-Fag

It is surprisingly successful in cases of cerebral exhaustion with digestive disturbance, and constitutes a mild, yet efficient invigorator in general brain-fag. "Byno" Hypophosphites restores tone to the heart muscle and arteries, and is a blood-producing agent as well as a concentrated nutrient.

'Byno" Hypophosphites is one of the best tonics ever put forward for combating the after-effects of severe illness or as a general invigorator when the system is enfeebled. It may be prescribed with confidence to enrich the blood, strengthen the gastro-intestinal functions, give tone to the nerves, and nourish and vivify the whole organism.

Prices: In bottles 3/- & 5/6 each. Sample sent free on request.

The 'Allenburys' Foods

Special Advantages

1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.

2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.

3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.

4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.

5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.

6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

Milk Food No. 1 From birth to 3 months.

Milk Food No. 2 From 3 to 6 months.

Malted Food No. 3 From 6 months upwards

The "Allenburys" Rusks (Malted)

A valuable addition to baby's dietary when 10 months old and after.

A descriptive Pamphlet, giving Analyses, etc., and Samples of the Foods will be sent on request.

SQUIRE'S

PHOSPHATE & GLYCEROPHOSPHATE PREPARATIONS.

GLYPHOCAL

SYR. GLYCEROPHOSPHATIS COMP. (SQUIRE).

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

GLYPHOCAL is indicated in **NEURASTHENIA** and in neurotic conditions. Immediate and striking improvement follows its exhibition. It is specially valuable in nervous affections accompanied by gastric weakness. It is very palatable and does not distress even the most delicate stomach.

GLYPHOCAL WITH FORMATES

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

GLYPHOCAL with FORMATES acts as a tonic to both the nervous and muscular systems, supplementing the valuable tonic properties of the **GLYCEROPHOSPHATES** with those of the **FORMATES.**

Strikingly successful in the **CONVALESCENCE** after **INFLUENZA** and similar affections.

GLYPHOCAL WITH FORMATES AND STRYCHNINE

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

GLYPHOCAL with FORMATES is of special value as a tonic in the abdomino-pelvic pain in women.—*The Practitioner.*

FEROCAL

SYR. FERRI PHOSPHATIS COMP. (SQUIRE).

DOSE—Half to one teaspoonful in water.

FEROCAL is the celebrated **CHEMICAL FOOD** originally introduced into this country by the late PETER SQUIRE.

FEROCAL is prescribed by the most eminent physicians throughout the world as the best means of increasing the **PHOSPHATE** metabolism of young and delicate children.

FEROCAL has been the **STANDARD PHOSPHATE PREPARATION** for over 50 years.

FEROCAL INVIGORATES, STRENGTHENS AND NOURISHES.

Illustrated descriptive leaflets gratis on application.

Telephones: Paddington 96; Gerrard 3485; Mayfair 3479. Telegrams: "Squire, Wesdo, London."

0·001 gramme, at 2/8 per box of 12

For Therapeutic Notes see Wellcome's Medical Diary

In the fourteenth century the Siamese dominated the Malay Peninsula as far as the seventh degree of latitude, these provinces not having yet been reduced to subjection by the all-conquering Mahometans. The Javanese, however, having newly joined the conquerors, attacked the peninsula. The King of Siam led a powerful army against the invaders, with the result that ancient Siam was one of the few countries that did not fall before the Saracen.

The Siamese warrior (date, A.D. 1300-1400), here depicted clad in magnificent armour, with mask and gilt helmet, is an example of the men who went forth to defend their country.

No. 1

No. 2

No. 3

No. 4

Prehistoric Burmese combats are recorded by quaint rock carvings, four of which are here reproduced. They represent the landing of an expeditionary force in ancient Burma, and what befell it. No. 1 depicts an enemy transport. No. 2 shows a native and an invader coming to an agreement. Each stretches out an arm, presses thumb against thumb, little finger against little finger, and allows the knuckles of the three remaining fingers to meet. In No. 3 an invading warrior is seen brandishing a sword and holding a prostrate native by the hair, whilst in No. 4 he is depicted holding the decapitated head of the native and dancing with exultation.

No. 5 No. 6 No. 7 No. 8

The history of an invasion of ancient Burma is continued in the following rock carvings. No. 5 shows the invaders in possession of the land on one side of a mountain whilst the natives are driven to live with the elephants on the other side. In No. 6, however, the tide has turned, and an invading transport is shown to have been sunk, the wavy lines indicating water above it. No. 7 depicts a native taking an oath in conjunction with kindred tribes—the number of these no doubt indicated by the lines above the tree—to eject the intruder. (Most of the uncivilised tribes of Burma still swear by a tree.) No. 8, the last scene, indicates the expulsion of the invader, a shower of arrows and stones accompanying him. Date, Prehistoric.

HOEFFTCKE'S EXTENSION APPLIANCES.

Ambulatory Treatment of Fracture of the Limbs; Tuberculous and Arthritic Disease of Joints.

By C. A. HOEFFTCKE,
7, Harley Street, London, W. 1.

(*Continued from Nov. 10th.*)

WHAT IS ARTHRITIS?

DISEASES of joints are mainly either of tuberculous origin or either septic, such as gonorrhœal, staphylococcal, streptococcal, or coliform.

Many of the latter group are vaguely called rheumatoid. On closer examination some of these cases may have their origin traced to some overlooked primary focus of infection, tonsil, teeth, intestine, &c. In others the cause is not traced satisfactorily.

The exciting cause of the disease in the joints can in the majority of cases be traced to an injury. At the time of the injury the joint is painful; the patient prevents the slightest movement. The blood-supply which has to bring the recuperative substances to the injured part is slowed down through non-exercise of the joint and offers a fair field to the invading bacilli.

A suitable vaccine or counter-irritation by means of massage, electricity, passive or active movements, may heighten the power of resistance in the blood, and by this means effect a cure, especially in very early cases.

When the disease is in a more advanced state and cartilage or even the bony surfaces are attacked the case seems almost hopeless. The pain does not allow the joint to be moved, the muscles contract through the patient's endeavour to bring fresh surfaces of the joint in contact, and deformity is the result. If the tension of the muscular tissues can be released and the joint surfaces pulled apart, in other words, if the joint is extended, the pain ceases and the joint can be moved. The normal blood-supply can be restored through the upright position of the body and exercise, and the joint surfaces recover, and so effect a cure.

To maintain extension between the joint surfaces many appliances have been invented, amongst which Sayres', Hessing's, and Thomas's splints figure prominently, but in all these the pubic bone has to bear the greatest pressure, which is painful; in consequence, the patient contracts his muscles and defeats the object of the appliance—namely, extension.

I claim for the appliance which I have invented that the weight of the body and counter-extension point is transmitted entirely upon the tuberosity of the ischium, which is adequately protected by the gluteal muscles, leaving the pubic bone quite free from pressure, so that the patient is enabled to walk and bear a continuous extension equal to 20 pounds or even more without discomfort.

The absence of pain in the joint when extended, the upright position of the body, and exercise improves the general health, which is also a mighty factor in the combating power of the blood-supply.

The ambulatory treatment with Hoefftcke's Extension appliance for tubercular and arthritic joints, and also for fractures, has been described and illustrated year by year since 1903 (stated in previous announcement as 1913 in error) by eminent surgeons and physicians in the leading medical journals, showing the excellent results which can be obtained by its application.

To make a comparison between the conservative treatment by means of rest and Thomas's splint and my ambulatory treatment I cite the following case, one out of a good many.

Miss R. A. Tuberculous hip.

Treated at first with weight extension in bed and afterwards with Thomas's splint for nine months by two of the leading surgeons of the Royal Orthopædic Hospital.

At the end of this time there was apparent shortening of about two and a half inches and an X ray photograph showed the head of the femur to be partially absorbed.

Another opinion was taken and my ambulatory treatment advised.

As soon as my Extension splint was applied the child commenced to walk and the general health improved rapidly.

After a time it was decided by the surgeon in charge to overcome the adduction. The patient was taken into Great Ormond-street Hospital for Children in the beginning of October, 1914.

The senior consulting surgeon subcutaneously tenotomised the adductors, and I manipulated and abducted the joint on my Extension table under an anæsthetic and reduced the shortening from two and a half inches to three-quarters of an inch. I then put the pelvis and both limbs in the abducted position into plaster, taking care not to release the extension, even for a second, during the operation or subsequent treatment, which is most important.

Three days afterwards the temperature was normal.

A fortnight afterwards I took the plaster off and adjusted my Extension splint to the improved position.

A week after the patient was discharged from hospital, walking well without the slightest pain, with fair movement in the hip-joint.

My splint was worn until April, 1916, when it was taken off at night, and in September, 1916, it was taken off altogether. The shortening is still three-quarters of an inch, which is not noticeable in walking. Instead of the patient having the usual stiff hip, with considerable shortening and a high boot, the result now is that after having been under my Extension treatment for two years since the operation the child is able to dance and jump about as well as any other healthy one, with perfect movement in the hip-joint, and has done so for the last year without any artificial help and without recurrency of the disease.

Many arthritic and tuberculous hip- and knee-joints have been treated in this way, with equally good results, of which I shall be glad to give particulars to any inquirers.

(*To be continued Jan. 19th.*)

A Discussion
ON
THE SURGERY OF
EXOPHTHALMIC GOITRE.

By T. P. DUNHILL, M.D.,
LIEUTENANT-COLONEL, A.A.M.C.; SURGEON TO ST. VINCENT'S HOSPITAL, MELBOURNE.

Methods of Treatment.

IN recent years divergent opinions have been expressed and written as to what is the best method of treatment for exophthalmic goitre.

I. It has been said that operation is the rational treatment, if one regards the manifestations of the disease as due to excessive activity of the thyroid gland. As one authority[1] has said: "If we could be certain that the essential and fundamental cause of the disease is the hypertrophy and over-activity of the thyroid gland, the most rational method of treatment would obviously be to reduce the enlarged gland to something like normal proportions by surgical means." Of those who hold this view some have regarded the operation itself as hitherto too dangerous to justify it being undertaken. The same authority at one time said: "Were it not for the considerable risk of life from the operation, I should not hesitate to recommend it as the most rational and practical method of treatment of the disease."

II. Others[2] have maintained that Graves's disease, as we know it, is not essentially due to thyroid gland activity, and therefore surgical treatment is theoretically wrong and practically useless.

III. Some think that the disease may be more successfully treated without operation. Rupert Farrant[3] has said that if hyperthyroidism were recognised and treated one to three years earlier Graves's disease would cease to exist. Hernaman-Johnson[4] and others say that the treatment should be by X rays.

IV. Kocher, the Mayos, Crile, and the writer believe that the disease can be practically cured by the removal of sufficient thyroid tissue when there has not been visceral degeneration, and can be greatly ameliorated in most cases even when this has occurred.

As I have now performed the operation for removal of thyroid tissue about 1500 times, I propose in the present communication to state what my own experience has been.[5] From half to two-thirds of the number have been cases of Graves's disease. Writing from a military hospital abroad I have not access to my records, but within a narrow margin my numbers are accurate. I have lived for a period of 11 years in the same town or State as most of my patients, and I have kept in communication with almost all of my private patients.

The Case for Operation.

The time seems opportune to present the case for operation, and to discuss what can be done by surgical methods. I take it that everyone wishes to get at the truth of the matter. He will not desire because he is a physician that the treatment should be solely medical, or because he is a surgeon that the treatment should be solely surgical, but in each case it will be his aim that the patient shall have that form of treatment which is most likely to bring about a cure. It ought to be possible to obtain some unanimity of observation among men who are working along different lines to the same end. If experiences could be exchanged; if, above all, men of divergent views could see the same cases before and after treatment, or before and after operation, it should help. Surgeons, as well as physicians, recognise that the removal of a large portion of a gland which is so essential to the bodily well-being as is the thyroid is a confession that the origin of its disturbances has not yet been discovered. But while recognising this, they maintain that the *manifestations* of Graves's disease are the manifestations of excessive and disordered functional activity of the thyroid gland. Working on this hypothesis, they believe that, when other means have failed, sufficient gland tissue may be removed to place the patient on a greatly improved plane of health, while still leaving ample for physiological purposes.

Physicians may pronounce against operation for two different reasons. Some think that operation gives no better results than medical treatment (using medical treatment in its widest application). Others, while recognising that removal of thyroid tissue favourably modifies the disease, consider that the risk of operation is too great: either the immediate risk of operation or the ultimate risk of insufficiency of thyroid. Their judgment is based partly on the result in their own cases which have been sent for operation and partly on the analysis of the published reports of surgeons. Some physicians send their cases for operation when a patient is losing ground, or if a reasonable trial of medical treatment fails to place a patient on an industrial plane.

We owe it to the multitude of sufferers from this disease—for there are a great many—that our minds should be free and open; not only that we should give every method of investigation and treatment its proper consideration and trial, but also that we should not persist in any method to the danger of the patient's life or to the detriment of the patient's welfare. In this article I shall briefly review my own position, stating the reasons that have led me to this position, and quoting cases to illustrate main points. Afterwards I will discuss some of the opinions differing from my own.

Reasons for Operating.

First, as regards reasons for operating. Eleven years ago, when in charge of an out-patient department, I happened to have under my care five or six patients with exophthalmic goitre who were not making progress. Then one other patient came who was very ill indeed. She had been an inmate of a hospital for some months and had had all the treatment that could be given. That patient brought me face to face with the position that something had to be done or she at least was going to die. That was the first outstanding observation. I was given the opportunity of operating upon her. The problem of safety of operation arose. I knew that some cases had been improved in health by operation. I also knew that some cases had died at, or as the result of, the operation. Kocher had published his earlier papers about operation under local anæsthesia. It seemed to me that along the lines of infiltration anæsthesia, together with lightness of handling and rapidity in operating, would lie the greatest measure of safety. For at that time it certainly was not a safe operation. I operated upon this woman, removing the right lobe. She so rapidly lost all the worst of her subjective symptoms and suffered so little discomfort from the operation itself that the other patients who had been associated with her in the out-patient room, on seeing her after the operation, one by one wished to be operated upon. They were all operated upon and all without general anæsthesia, and none of them died. Whatever may be my views now, there was no doubt in my mind then, nor was there in the minds of the physicians who saw these cases, that the infiltration with local anæsthetic was the chief factor in making for the safety of the operation. Nor is there any doubt that, in those days at any rate, it was the knowledge that the operation could be performed without general anæsthesia which mainly induced patients to present themselves for operation and physicians to permit their patients to undergo operation. To most of these points it will be necessary to recur, but for the moment the record of the evolution of one's position is being traced.

Results Depend on Removing Sufficient Thyroid Tissue.

In 1907 A. Kocher wrote: "We find it rarely necessary to resect a part of the remaining gland after excision of one side. We have cured by our operation the patients in 83 per cent. of all our cases."[6] After some months I knew that this was not going to be my own experience except in some cases that were very mild. The worst cases gave the most striking results so far as they went. But these results were far short of cure. The psychical unrest would disappear, as would the feeling of tenseness and strain in the eyeballs. Much of the tremor and the consciousness of arterial throbbing would vanish. If there had been amenorrhœa there would be restoration of the menstrual function;

[4] Pract., July, 1917.
[5] See also THE LANCET, 1912, i., 422.
[6] The Surgical Treatment of Exophthalmic Goitre, Jour. of Am. Med. Assn., Chicago, 1907, xlix, 1240-12 4.

there would be some reduction in pulse-rate, but not to normal; there would be less palpitation, but it would not disappear completely; there would be improvement in colour and almost always gain in weight. Often there would be improvement in growth of hair if this had been thin.

This constituted a great improvement in the patient's condition, but it was not a cure. If it was left at that, and the patient returned to work, there was frequently a return of the distressing symptoms. This was not a satisfactory position for the patient or for the surgeon.

The return of symptoms is readily understood. The remaining lobe still is usually greater than the whole of the normal gland, and it is more active. Also, ligature of its arteries has never, in my experience, made the slightest difference in the size or activity of a lobe. Within the first six months of beginning to operate one had realised that removal of more gland substance than one lobe was necessary, if one was to place a patient on an "industrial" plane. I then decided to remove a portion of the second lobe when necessary, working from below upward, so as to remove the larger lower pole, while leaving the smaller upper pole with its feeding vessels absolutely undisturbed.

I now found that the percentage of cases practically cured was high; that girls were able quickly to go back to their work and to enjoy their recreations; they completely lost the feeling of bodily heat, and palpitation; their pulse-rates became normal. Still, even after a second operation, in a very small percentage of cases operated upon, it would happen that while almost all the symptoms had disappeared some few, or only one symptom would remain. Generally, in these latter cases, one would recognise that the upper remaining portion of the lobe was obviously bigger than one had judged at the second operation. For, as has been said above, the portion of gland to be left is never dislodged from its position, even to see how big it is. I have written before about the tongue-like process which frequently passes behind the trachea from the posterior border of the gland.[7] Thus one is not able to judge quite accurately. Moreover, the patients are sometimes desperately ill. It is always essential in such cases rapidly to make up one's mind how much it is safe to remove, and very rapidly to complete what one has decided to do. The immediate safety of the patient is always the first consideration. On the other hand, it has sometimes seemed as though there were no excess of gland tissue remaining, no prominence over the remaining part of the upper pole. And yet on operating one has found a mass of thyroid tissue as big as a hen's egg partly behind the larynx and partly behind scar tissue in the neck. The complete recovery from the remaining symptoms after the removal of portion of this—while still leaving sufficient for physiological purposes—is most striking.

To recapitulate: I have always found that removal of one lobe and the isthmus gives improvement which is readily recognised by both patient and observer. The removal of rather more than half the remaining lobe almost always places a patient on a plane of health which enables her to work and play and to feel well whilst doing so. Occasionally a third operation is necessary. When necessary it is generally because one has not been able to judge how much was left at the second operation. The reason one is not able to judge is because the portion to be left is never dislodged.

Illustrative Cases.

I have selected the following cases to bring out certain points. Each two cases are chosen to illustrate one striking symptom or aspect. In some, the photographs show this best (although the photographs were only taken for the interest, at the time, and not for publication). In others, the history is such that it is convincing.

Cases with Much Emaciation.

CASE 1 (Fig. 1A) is that of a woman who had suffered from exophthalmic goitre for about two years. She had had treatment all the time, and had been in a nursing home for about six weeks before I saw her. The photograph speaks for itself as regards the emaciation. The tremor was typical, and in this case the pulse was almost uncountable. There was much vomiting at intervals all through the illness following, but not preceding, its onset. There had been amenorrhœa for nine months. All that could be done by medical treatment and by rest in bed had been done, and the patient was becoming worse. There was no source of toxic absorption that could be detected. Teeth, tonsils, accessory sinuses, bowels, generative organs were apparently healthy. Rest in bed had been carried out, and the patient was obviously nearing the end. With novocaine infiltration anæsthesia I removed one lobe and, later, half the other. I append a photograph (Fig. 1B) of the same woman some months later. These photographs scarcely need comment. One could not conceive a woman more ill than this one was. She is now looking after her husband and is performing her household duties.

CASE 2.—With her I will class a nursing sister (Fig. 2, whom I was asked to see by Dr. W. Pasteur, senior physician to the Middlesex Hospital, London. This sister became ill during the latter half of 1916 and was invalided from her duties. After a period of rest she returned to duty. In 1917 she became much worse, and even after three months' complete rest in bed she was too ill to travel home. Dr. Pasteur gives me permission to state that, when he asked me to see her, he told me that he considered her too ill for operative interference. She had lost 5 stone in weight. The eyes were staring. The pulse-rate, as shown by the chart which I append, was frequently over 150, and not infrequently over 160, after having been for some weeks in bed. The tremor was typical, and she was acutely distressed by the constant sensation of internal pulsation. She had much gastro-intestinal unrest, with severe attacks of vomiting, following but not preceding, the onset of Graves's disease. The patient had been in bed for 12 weeks. The weight had fallen from 12 stone to 7 stone. This sister had formerly been able to lift up another sister horizontally in her arms. Her muscular weakness was now extreme and she was dangerously ill. She was operated upon on May 25th under novocaine infiltration anæsthesia. In five days all abnormal sensation of pulsation had disappeared. The appetite was good. The patient was a happy woman, but the pulse was not normal. This woman is compelled to earn her own living as a nursing sister. If she had returned to work without more being done the symptoms would have recurred, because only one lobe had been removed. There remained still a distinct isthmus and the right lobe. Almost always the isthmus is removed with the first lobe. This woman was far too ill for anything more than the minimum to be done at the first operation. On June 15th I removed the enlarged isthmus and the lower half of the right lobe. I publish the chart of this case. It shows that on the eighth day after the second operation—that is to say, almost at once after sufficient gland had been removed—the pulse dropped to the eighties and remained there. It rose to 120 on one day for a few hours only, the day when her menstrual period was due. Since then it has never been raised. It is now in the sixties in the morning and in the eighties at night after being up and about. I append two photographs of this woman (Fig. 2A and Fig. 2B), one taken ten days after the second operation, whilst she was still emaciated, and one taken three months afterwards. She is still gaining weight every week.

These two cases are published, with their photographs, to show the degree of emaciation which may occur, to show that even in these cases the operation can be performed with reasonable safety, and to show the obvious improvement after a sufficiency of gland tissue has been removed. All tremor has gone; all feeling of eye-strain has gone. All palpitation and sweating have gone, and the patients feel completely placid and restful. Their pulse-rates are normal.

Cases with Extreme Proptosis.

I will now speak of two cases in each of which the proptosis was so extreme that the conjunctiva became œdematous and overhung the lower lids. It appeared as though it were strangulated. The eyelids could not be closed voluntarily. In one ulceration through the cornea of one eye occurred with extrusion of the lens. In both the eyelids were stitched together for a period.

CASE 3.—Miss J. (Fig. 3) was a stout woman, and she had lost no flesh, but she was very ill. There was tremor and the pulse-rate was very rapid. The exophthalmos was extreme, the conjunctiva in each eye being œdematous, and overhanging the lower lid as though it were strangulated. I removed one lobe of the thyroid gland and the patient was improving, when she got an attack of influenza and bronchitis. The constant coughing, together with the associated coryza, made the eyes much worse somewhat suddenly. The cornea of one ulcerated, and in spite of constant attention by an ophthalmologist the ulcer deepened in the œdematous and inflamed conjunctiva, and extrusion of the contents of the eyeball occurred. I removed half the second lobe to lessen the absorption of the thyroid secretion, and Dr. Edward Ryan sutured together the eyelids of the remaining eye in order to protect the cornea. The pulse-rate dropped to the eighties and the sound eye receded. When it was judged safe the eyelids were separated and then the disorganised eye was enucleated. It was long before the cornea haze disappeared from the sound eye, but now she can read well. A glass eye has been fitted, and one would not know that she had ever suffered from exophthalmic goitre. She lives her normal life.

[7] Med. Annual, 1913, and Brit. Med. Jour., 1909, 1222-1225.

Fig. 3A is not in good focus, but it shows the salient features. The bulging forward of the eyes above the lower lid can be seen and the raising of the outer half of the eyebrow. It was taken after the first operation. Fig. 3B shows the same woman now.

I want to mention briefly a similar case.

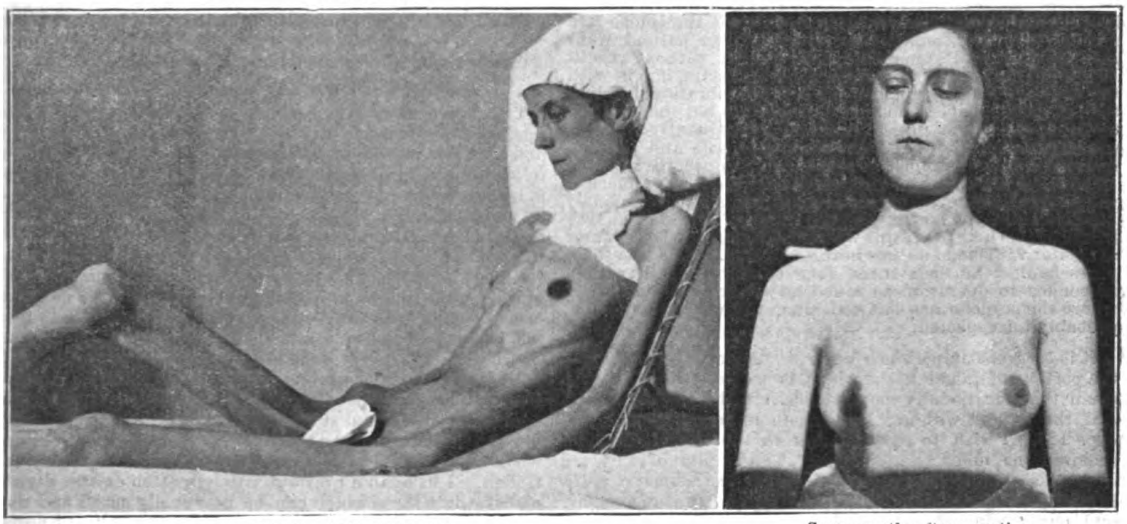
CASE 4 was that of a man whose eyes were proptosed to such an extent that the conjunctiva was œdematous and bulging beyond the eyelids. His legs, thighs, and lower part of his abdomen were dropsical and œdematous from the heart failure; the apex beat was three-quarters of an inch outside the nipple line and the pulse was extremely irregular. The goitre was very large, as I have frequently found it in men who suffer from Graves's disease. I will not go into the details of the operation more than to say that I was compelled to remove what was necessary in three stages. The gland was so big, so friable, and so very vascular—the hæmorrhage being very severe on cutting across the gland tissue—that each time it was imperative very rapidly to remove just what one felt one safely could. Quite a large piece was removed each time. What remained after the second operation appeared to be as large as a cricket-ball. A severe cold with much coughing supervened immediately after the third operation. He could not voluntarily close his eyelids, and the œdematous, bulging conjunctiva became inflamed. The cornea became hazy from exposure. The conjunctiva appeared to be strangulated. As in the last case, the eyelids were sutured together to protect the eyes. This was done by Dr. Ryan.

The eyes receded a great deal and the lids were separated. The heart's apex has come in considerably, the œdema of the body has completely disappeared, leaving lineæ bicantes. The pulse remains irregular, but not unduly ast. In this case there was, of course, an advanced grade of isceral degeneration, as shown by the dilated heart, the regular pulse, the back pressure with ascites and œdema. One cannot cure where heart muscle has become degenerate, but having removed the poisoning agent it is wonderful what power of recuperation a heart even in this state has. The improvement begins immediately sufficient gland has been removed. I publish his photograph (Fig. 4). It was not possible, in separating the eyelids, to divide between the lashes of the upper and lower lids. The separation had to be done partly at the expense of the lower lids. This is seen to be particularly the case in the outer half of the lower lid, but the upper lid is seen to come well down over the upper margin of the iris. I regret that I have not a photograph of this man before operation to show the proptosis, but he was far too ill.

It may not appear to be worth while to do this amount of work for a result which, in a case of visceral degeneration, cannot be perfect. But it has transformed a man who was bedridden dropsical wreck, with eyes almost out of his head, into a man who is able to walk about freely, and to be a comfort to his wife and child.

I have published the notes of these two cases to show that the eyes may recede, if sufficient gland tissue is removed, even when the proptosis has been extreme.

The last patient belongs to a class of cases which most writers regard as unsuitable for operation, chiefly on account of the danger of operation, but also because the extent of visceral degeneration is thought to preclude any considerable degree of improvement. I can state definitely that great improvement follows operation if the gland is still in a state of increased activity, and I have never lost a case of this type of operation. It goes without saying that for this type local anæsthesia is absolutely essential.



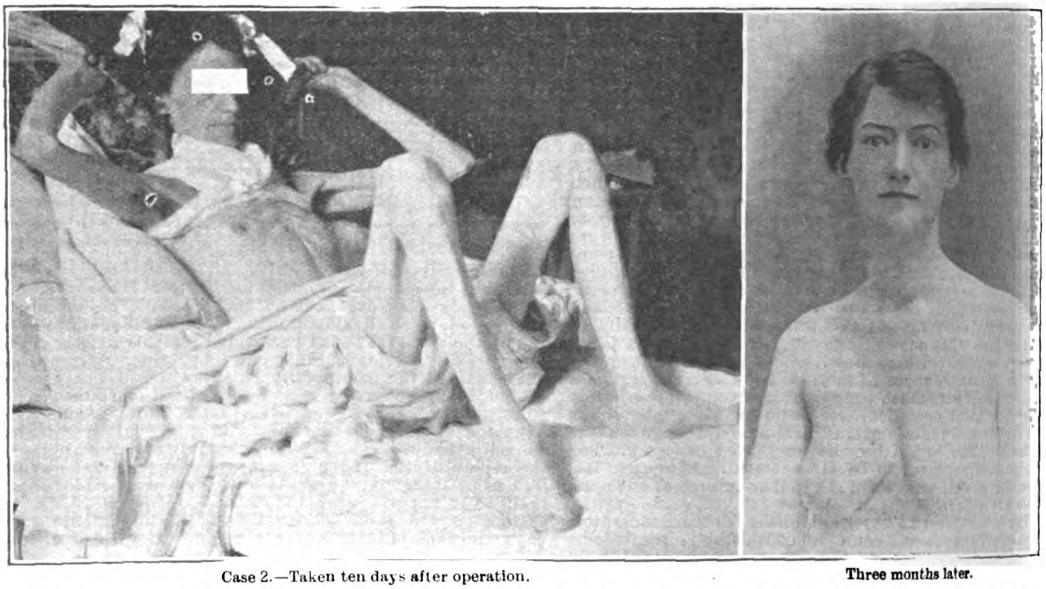
Cases showing Need of Removing Sufficient Gland Tissue.

I wish to speak of two cases, in each of which it was necessary to operate a third time, in order to get rid of some one remaining symptom.

CASE 5.—Miss M. was a healthy girl in the early twenties, when she developed exophthalmic goitre. The goitre, the prominence of the eyes, the tremor, the rapid pulse and the palpitation, were all characteristic. The first operation was one of the first six that I performed for this disease (1906). Consequently I removed only one lobe. She was improved, but remained far from well. This was the first case which compelled me to recognise that removal of one lobe was not going to cure, and I removed a part of the second lobe. After the second operation she lived a fairly active life, but she still had a large piece of gland tissue remaining in the region of the upper pole of the left lobe and was not free from tremor and palpitation. Her eyes had become practically normal after the second operation. I decided to remove still some more. This I did, and within a few days she felt quite a different being. Her eyes are now normal, her pulse is normal, she has no tremor and no palpitation. She has undertaken a tour on foot, lasting five days, over mountains, carrying a knapsack, and sleeping at nights in ordinary accommodation houses. She plays tennis regularly and is quite well. This was not due to rest in bed or medical treatment. Each time she entered hospital the night before the day of operation. As soon as *sufficient* gland tissue was removed she was completely better. Ten years later her health is normal. She is a vigorous woman.

FIG. 1A.

FIG. 1B.



Case 1.—Before operation. Some months after operation.

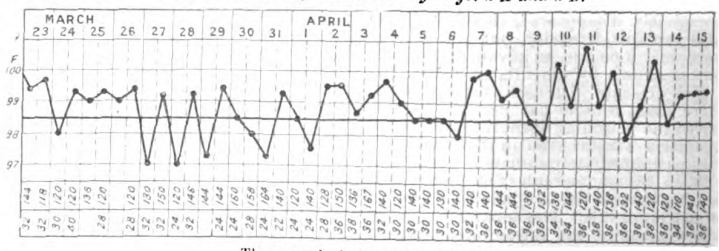
The effect of the third operation in the next case of which I shall speak is most striking. A typical case, she was first operated upon by a colleague of mine and one lobe was removed. She considered herself sufficiently better to dance and do housework. During the absence of her surgeon abroad she became worse. The heart dilated, with the apex beat well outside the nipple line, and the pulse became irregular. The remaining lobe, always the larger of the two, was very big.

It was necessary to operate, because one saw her becoming steadily worse. Rest in bed had no effect. Two-thirds of the remaining lobe were removed. Following this, the eyes, which had been decidedly proptosed, became normal. The pulse lost all irregularity except on the rarest occasions. The apex of the heart came to within the nipple line and the pulse rate fell to normal. But the tremor remained and was most distressing. There appeared to be no excess of thyroid gland tissue, and for about two years I watched her

FIG. 2 A. FIG. 2 B.

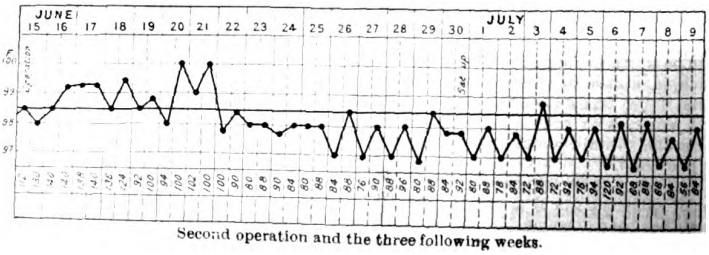
Case 2.—Taken ten days after operation. Three months later.

in this condition. The eyes were normal, the pulse-rate normal, but the tremor was obvious. The patient went into hospital and remained there resting without result. Drugs did not control the tremor. On shaking hands with her she gave a firm grip, and one felt the vibration. It was then decided to open the neck through the old incision and to see if there was not, as one had so frequently found, a prolongation backwards from the upper pole and postero-internal border behind the larynx and upper part of the trachea. I did this, and discovered that there was a piece of the thyroid tissue, as big as a small hen's egg, completely hidden behind the larynx and the trachea. I removed two-thirds of this and the result was most dramatic. Every trace of tremor vanished and has never returned. This was three years ago. I am convinced that cases which have not responded to operation as much as was expected are cases where the surgeon has left too much thyroid tissue behind, probably unsuspected.



It is of great importance never to dislocate—or handle—the portion of gland tissue which is to be left. This will mean that occasionally more will be left than one suspects, and the patient will not be as much improved as one had expected. I wish to say here that in this case I probably removed too much gland tissue. The results of this are that occasionally this patient feels slight rheumatic pains in the right wrist. There are no other symptoms of deficiency, and one grain of dried thyroid tissue a day clears up the wrist pain when present. One might doubt the connexion if it were not for the effect of the administration of the small dose of gland tissue. The proptosis, irregular heart-beat, palpitation, and tremor, which made her very ill, are all gone, and she now lives a very active life, with the sole discomfort of occasional stiffness or slight pain in one wrist. Strangely enough it is only in the one wrist.

The preceding two cases are recorded to show how necessary it is to remove sufficient gland tissue if one is to obtain a result approaching a cure. And yet one must never overdo it. There are few surgical operations where the same degree of judgment is required.



Disabled Cases Greatly Improved by Operation.

Two other cases are extremely interesting. Each had reached the stage of cardiac dilatation with irregularity of pulse. Each was operated upon as a last resort. These two, following the operations, have each lost all irregularity of pulse, except about once a fortnight. Then for from 12 to 24 hours the heart will begin to beat irregularly and to cause the greatest discomfort. After about 24 to 48 hours the irregularity ceases as suddenly as it began. For about a fortnight again they each work exceedingly hard, with a quite regular pulse, and they feel safe until the next turn comes. This may not seem a very good result, but these two cases were quite disabled before operation. One was bedridden. They were operated upon to try to prolong life, not with the hope of effecting a cure. After four years these two are still holding their own to the same extent. One manages an hotel and store. The husband of the other has gone to the war, and she manages her house and two children without a servant. This is the one who was completely bedridden. I have in a previous article written on the division of cases into those which can be practically cured and those which—through degeneration of cardiac muscle, as evidenced by irregularity of pulse, dropsy, or albuminuria—cannot be cured but may be greatly improved.[s]

Chart of Case 2, illustrated by Figs. 2 A and 2 B.

Three weeks before first operation.

Second operation and the three following weeks.

Further Discussion of the Case for and against Operation.

I have published more or less detailed notes of these eight cases to show what can be done, and done fairly safely, by one who has the requisite judgment and skill, and to show what measure of improvement may be expected to follow.

[s] Dunhill: Brit. Med Jour., May 22nd, 1909

In all the cases the patients were exceedingly ill. Six of them were so ill that few practitioners would have regarded them as having much chance of living, much less of improving. And these eight cases are selected from a great number of similar cases. In this article I am not giving detailed descriptions of the disease nor describing operations upon cases of the subacute or chronic type, cases that are holding their own without getting much better or worse. I have done that in previous articles.[9]

I do not say that every case should be operated upon, and I am far from saying that every case should be operated upon at once or even early. But I want both physicians and patients to know what can be done and how it can be done with reasonable safety.

Hale White states that 50 per cent. will be cured by ordinary medical means. I think it will be admitted that this 50 per cent. will include early and mild cases—cases which are still definitely Graves's disease—as seen by a physician in his private or hospital practice. When people begin to feel unwell they consult their family doctor or a physician, not a surgeon. Surgeons very rarely see early cases.

Of the operation results collected by McCarrison he puts down the average percentage of cures as 60. He says that this is not a sufficient improvement on the 50 per cent. cures due to medical treatment to justify the risk of operative mortality. I do not wish to argue on statistics, but it is necessary to point out that whilst the medically treated cases include all early and mild cases, the surgically treated cases are practically all cases which have come through the medical filter—i.e., they are cases which have only been permitted to come to the surgeon after medical treatment has failed to improve them. So that the 60 per cent. cured by surgical means is really 60 per cent. of the remaining 40 per cent. which medical treatment has failed to cure.

Marine and Lenheart, as a result of their histological work, state that:—

"The differences between the pulse-rate of the normal or colloid glands and of the most marked active hyperplasia are so slight as to bear no suggestion of any causal or effect relation. If any relation exists, the objective evidence would tend to indicate a hyposecretion rather than a hypersecretion, since the pulse-rate bears no relation to the amount of secreting surface, and a negligible relation to the histological structure of the gland."

One recognises the very high order of the work done by these two observers, yet it is difficult to make their findings accord with observed clinical facts. Removal of hyperplastic tissue causes an immediate drop in pulse-rate. The chart which I have published is that of a woman who had been in bed for a long time. She had had the best medical attention. She was not holding her own. Dr. Pasteur gave it as his opinion that she was too ill to stand operation. The chart after the operation speaks for itself. This can be observed in every case when once sufficient gland tissue is removed. The drop in the pulse-rate follows removal of tissue, and it follows quickly, and it follows when neither rest, nor medical treatment, nor elimination of toxic sources has been able to do it. And it follows when patients have reached the stage when surgical interference is, to say the least, a hazardous proceeding.

If in the case of a person severely ill with Graves's disease the state of the thyroid were hyposecretion the removal of three-fourths of the gland should cause myxœdema at once, and fairly constantly. Yet it never does, either immediately or later. On the contrary, one can show the loss of psychical unrest and a condition of physical well-being which, before operation, was foreign to the patient.

FIG. 3 A.

Case 3.—Taken after first operation.

Present day.

FIG. 4. (Case 4.)

Results of Medical and Surgical Treatment.

McCarrison says:—

"There is no definite proof that the cures effected by surgical means (i.e., by hemithyroidectomy alone, or with ligation of arteries) are more lasting than those effected by medical means. As judged by these results hemithyroidectomy possesses little advantage over medical treatment. It may result in some amelioration of the symptoms, but this might reasonably be considered to be due in part to the enforced rest in bed."

One would like to point out in this respect that *hemithyroidectomy* is not the operation which is performed for the cure of Graves's disease. In 1909 I wrote in the *British Medical Journal* that it was necessary to remove portion of the second lobe (always leaving sufficient for physiological purposes).

Later, Halsted wrote of the necessity for partial *double* lobectomy for the cure of the disease. The Mayos and Crile have written similarly.

Hemithyroidectomy, even with ligation of arteries, has never, since 1907, been regarded as the operation for the cure of Graves's disease.

McCarrison also writes that it is no use swelling the literature with reports of cases "cured" by thyroidectomy without the fullest information concerning each case. The cases I have given are typical of the cases which come to the surgeon from the physician. I could multiply them indefinitely. Yet on carefully searching through McCarrison's book I am able to find only one case of Graves's disease from his personal experience with any details given.

In the often slow evolution of the disease, in its very chronicity, lies the danger. The patient who is anxious to be better and the practitioner who is anxious to avoid operation may each be lured into thinking there is an improvement, or that, at least, the patient is holding her own, or that time is of no moment, while the best years of a woman's life are slipping by. Too often the apex of the heart is creeping out, visceral changes are taking place, and the proptosis is becoming permanent. The woman is ceasing to be able to occupy her usual position

[9] Dunhill: Brit. Med. Jour.; Proc. Roy. Soc., 1912; Med. Annual, 13.

in the social order. I grant almost all that they say to those who, like McCarrison, state that the search for the cause should be relentless and unceasing. But while the cause is being sought for, patients must not be allowed to die, and more than that, they must not be allowed to lose the best years of their lives or to sink into a condition of visceral degeneration. One does not allow patients to die of appendicitis or of cancer whilst one is searching for the cause. They both have causes. The conditions which we call appendicitis and cancer are the results of some pre-existing cause. When the condition is established and is menacing life we deal with it as such, whilst all the time the search for the cause goes on. Some pre-existing condition pulls the trigger to start the thyroid on its dystrophic course. If the patient, though ill of the disease, is still well enough to be the subject of prolonged investigation, this should be done, and no stone should be left unturned to discover the cause But this course should not be obstinately persisted into the peril of the patient The following incident is related to show to what extent the search for the cause may be pushed.

A woman of 24 years had all the cardinal symptoms of the disease. The eyes were greatly proptosed. She was being treated by a goitre specialist, who had followed the recent work on the septic origin of the disease. He had sent her to a rhinologist who had removed her tonsils. He thought this was not efficiently done, so he sent her to another to have them enucleated. Then a deflected septum was attended to. Following this, some of the accessory sinuses, ethmoidal or sphenoidal, were cleaned out. Next she had a prolonged course of X ray treatment. He then was about to compel her to have all her filled teeth extracted—which meant almost all her teeth—because "the disease is always due to a septic focus; you are not cured by what had been removed, therefore it must be your teeth." At this stage she asked to see me in consultation. A dentist pronounced the teeth well filled and sound. Her troubles had been going on for some years. One lobe and half the other were removed at one operation, with much greater relief than had followed all the previous treatment.

If rhinologists say the septic focus is in the naso-pharynx and accessory sinuses, and the "intestinal stasis" men say that the cause is in the alimentary canal, the patient will have to travel a long lane before she comes to the turning. Septic foci should always be removed before anything further is done. Tonsils, teeth, sinuses should be investigated, as well as abdominal condition, and thoroughly—but with wisdom, judgment, and restraint.

Re X ray treatment: The difficulty of preventing burns has, I believe, been overcome. It is not so easy to judge how much active gland tissue the rays will destroy. The effects, I understand, continue after the application of the rays. I do know of one case in which myxœdema followed X rays. And I do know of cases which have had to come to operation after X ray treatment has proved ineffective.

It is a question whether one can more accurately judge the amount to be left by operation, where one can leave an upper pole with its own blood-vessels quite intact and fully functional, or by X ray, with which one does not know the exact amount or extent of cell destruction.

I can vouch that it is a fact that whatever is left after operation does not atrophy, but rather tends to increase in size. Also, from carefully reading Hernaman-Johnson's paper, I think there is no doubt that the degree of improvement following operation is much greater than that following X ray treatment.

Questions of operative technique, anæsthesia, safety of operation, death-rate, division of cases into types, and the response of different types to removal of gland tissues, amount to be removed, and best time for operation, importance of parathyroids—all of these must await a later article, when I can obtain access to my own records.

MEMORIAL SERVICE IN LONDON FOR THE LATE DR. ELSIE INGLIS.—At the service held on Dec. 6th at St. Margaret's, Westminster, in memory of the late Dr. Elsie Inglis, the Bishop of Oxford analysed the qualities which had made her life so fruitful of results. Personal surrender and warm sympathy were combined in her with the gift of organisation and of wise government. Twice she had rescued the Serbian nation from despair by her splendid courage, and her name was revered by the Serbians almost as one of their legendary heroes. Representatives of the Allied Governments were present at the service, including Mr. Balfour, Lord Robert Cecil, and Sir Alfred Keogh. The Red Cross Societies and various Women's Societies were strongly represented.

NASAL RECONSTRUCTION.

WITH A NOTE ON NATURE'S PLASTIC SURGERY.

BY J. L. AYMARD, M.R.C.S., L.R.C.P. LOND.,

CAPTAIN, R.A.M.C. (T.); LATE PLASTIC SURGEON, CAMBRIDGE HOSPITAL, ALDERSHOT; EAR, THROAT, NOSE, AND PLASTIC SURGEON, THE QUEEN'S HOSPITAL FOR FACIAL INJURIES, SIDCUP, KENT.

TIME and other conditions being favourable, it would have given me the greatest pleasure to have published my failures of the past 18 months in their entirety. I would, however, point out that such failures, accompanied by any small success I have achieved, are duly noted and illustrated in the records of the Queen's Hospital.

My excuse for writing this article must be that opportunity has perhaps placed me in a favourable position with regard to ample material. Whilst flaps and methods for reproducing the complete nose have in the past been fully written up in most surgical text-books, the causes for failure are hardly ever dealt with, and details of the work are sadly deficient.

Let me start by reminding those who have not seen cases prior to operation that almost the *greatest difficulty* presenting itself is the fact that when the nose has been destroyed by war injury the scar tissue surrounding the lost organ has to be utilised for the junction of the new flap. The most common cause of failure is probably due to the fact that the nasal cavity is not an ideal aseptic one any time, but rendered much more unhealthy owing to the inevitable damage to one or more of the sinuses and their surrounding tissues. This cause of failure has been partially due, certainly in my own case, to undue haste, in not recognising the Golden Rule—that no plastic operation of any kind can possibly suffer through reasonable delay.

The Principle of Nasal Construction.

One is so apt to formulate principles only to discard them later that I feel somewhat diffident in attempting to do this. However, I think most rhinoplastic surgeons will agree with me that the following require attention:—

The *flap* should be taken, if possible, from the site likely to lead to the least ultimate disfigurement. The *lining of the flap* should take some form other than scar tissue. The *new organ* should, as much as possible, correspond with the original. The *supporting framework* should, as closely as possible, simulate the original. The *bed area for the new organ* should be most carefully prepared.

Having relieved myself of these ideals, I will show later how I produced a fairly respectable organ by unintentionally almost discarding them.

The Flap Taken from the Forehead.

The side from which this is taken depends entirely upon the largest area free from hair.

The second case described shows a new method I am trying. It consists in taking a long pedicle flap with its base near one clavicle, and forming the nose upon the chest on the opposite side, keeping the head slightly bent upon the chest for 14 days.

I have adopted this method, not because I am entirely disappointed with the forehead scar, but because, if successful, the advantages in time, &c., would be considerable.

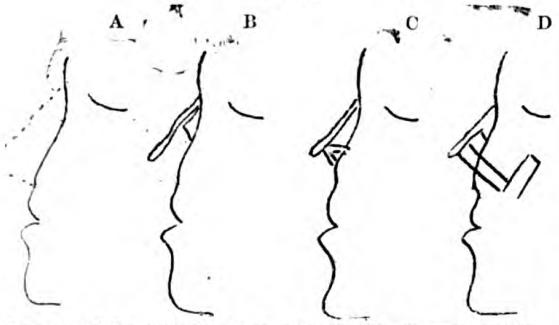
If this chest flap fails, I shall then resort to two flaps as used in the first case illustrated (Fig. 2), that is to say a small forehead flap and alar flaps from the cheek. The above, of course, may have to be modified owing to the presence of extensive scar tissue.

The Question of Lining Nasal Flaps.

The necessity for some form of covering other than scar tissue presenting internal to the nasal cavity is generally admitted. I endeavoured to overcome this difficulty by removing the entire periosteum, and I think failure was often due to a mild septic infection. The argument as to the delay in healing over bare bone is, I think, counterbalanced by the fact that the slower the growth of the scar the better the result. Whether the whole of the skin flap should be epithelium or part epithelium and part covered with mucous membrane remains to be seen.

Resemblance to Former Organ.

I have had not only the advantage of a skilful sculptor Mr. Edwards—but also the invaluable services of Professor Tonks upon these points. However ideal it may seem, at



no matter how much one falls short of this ideal, I feel certain that it is advantageous, and its employment will assist us in the near future in producing fairly constant and satisfactory results. In the first case (Fig. 2) I made the most accurate calculation as to skin and cartilage from sections of the sculptor's model, and, but for the inevitable accident of partial sepsis, the result would probably have been a faithful copy.

The Supporting Framework.

Should these be cartilage, bone, or a combination? I am in favour of all cartilage framework. Cartilage will attach itself to bone exactly as bone will to bone, and the resistance of cartilage to mild sepsis is an argument in its favour, and, further, we know that cartilage remains a constant, whereas bone unattached is prone to disappear.

Possibly, in the near future, the exact supporting structures of the nose may be copied in their entirety, but for the present we must be content with other methods. In Fig. 1, A represents the artist's model; B, what I designate the "diving-board" principle of support—that is to say, the bank represented by one or more layers of cartilage, and the spring-board the overhanging cartilage. The bank portion of this principle is an essential to success, and whether built up by turning down a skin flap or by turning up the turbinate bones by Seccombe Hett's method is a matter of choice. The essential to success is, that in some form or

FIG. 1.

Diagrams of the supporting framework for the new nose. A, The sculptor's model. B, The diving-board principle. C, The road-stop principle. D, The diving-board and swung septum.

other, the prominence due to the lost nasal bones must be reproduced. Without support to the free end of the "diving-board"—viz., the cartilage—only indifferent success will be attained. Fig. 1 C represents the trestle principle with lateral supports. Where lateral supports are used, in order to be certain of any success, they have to be made of considerable strength. Personally I am now in favour of D, the septal support swung forward where possible or the alternative of a new septum as recommended in Holmes's "Surgery" 50 years ago. I have in mind an excellent rigid septum made by Lieutenant Seccombe Hett. He dissected up two flaps of mucous membrane, between which he inserted a mass of cartilage 2 in. by 1 in. by ⅛ in. which I dissected from the eighth costal. If this can be done at the same period at which the other cartilage is inserted under the skin, then I think a great deal will have been attained.

The preparation of the skin area upon which the new nose is to be embedded. Great care must be given to this stage, and it is advisable to undercut the skin and tissues in order to contract the opening and bring healthy new tissues into the region for this purpose. Re-formation of the lip is frequently necessary.

Illustrative Cases.

CASE 1.—The photograph (Fig. 2 A) shows the case of a man with total loss of nose, right eye, and middle portion of his lip. In this case the cartilage shaped was introduced beneath the periosteum and the whole turned down and fixed in proper position at one operation. If the first photograph is referred to the amount of scar tissue to be dealt with can be readily seen. I formed the new lip at a separate operation, but a mass of scar tissue remained into which the new nose had to be implanted.

The second photograph (Fig. 2 B) shows the new left ala and lip which were made from a cheek flap. A portion of the right ala still remains to be formed, the wrinkles under the left eye can be removed, and the right lower eyelid raised. The hollow, sunken appearance of the right eye will be seen to have been overcome in the second photograph. This I brought about by the introduction of my cartilage sphere.[1] The man has considerable movement with the glass eye. Many other records and details of this case can be seen at the Queen's Hospital. There is no nasal stenosis.

CASE 2.—This illustrates a method of building the new nose upon the shoulder and transferring the same temporarily attached by a long pedicle. If this method succeeds it has the following advantages: absence of forehead or face scars and time.

Oct. 15th, 1917: I introduced the cartilage under the skin—one piece about 2½ inches long to form the main support and two lateral pieces at right angles and underneath the same. These are shown in the diagram Fig. 4 (1 and 2). The diagram, Fig. 4 (3), also shows the shape of these cartilage pieces. On Nov. 12th I performed the second stage of the operation in conjunction with Lieutenant Seccombe Hett. This consisted in separating and undercutting the pedicle from A to B and sewing it together tube fashion, Fig 4 (2). Between B and C below the skin was incised and undercut to the upper B and C, and an epithelial graft was introduced upon rubber. The raw surface between AA and BB was undercut and drawn nearer together, leaving an inch of raw surface.

The objects of this portion of the operation were: firstly, to provide the necessary lining for the nose, secondly to render the pedicle as free from granulation and suppuration as possible by folding it together, and, further, by partial detachment to favour the blood-supply in the right direction. The transfer to the correct position will, if all goes well, take place in about three weeks.

The further notes on this case denoting either success or failure will be supplied by Major Gillies and Lieutenant Hett, in whose able hands I must now leave the case.

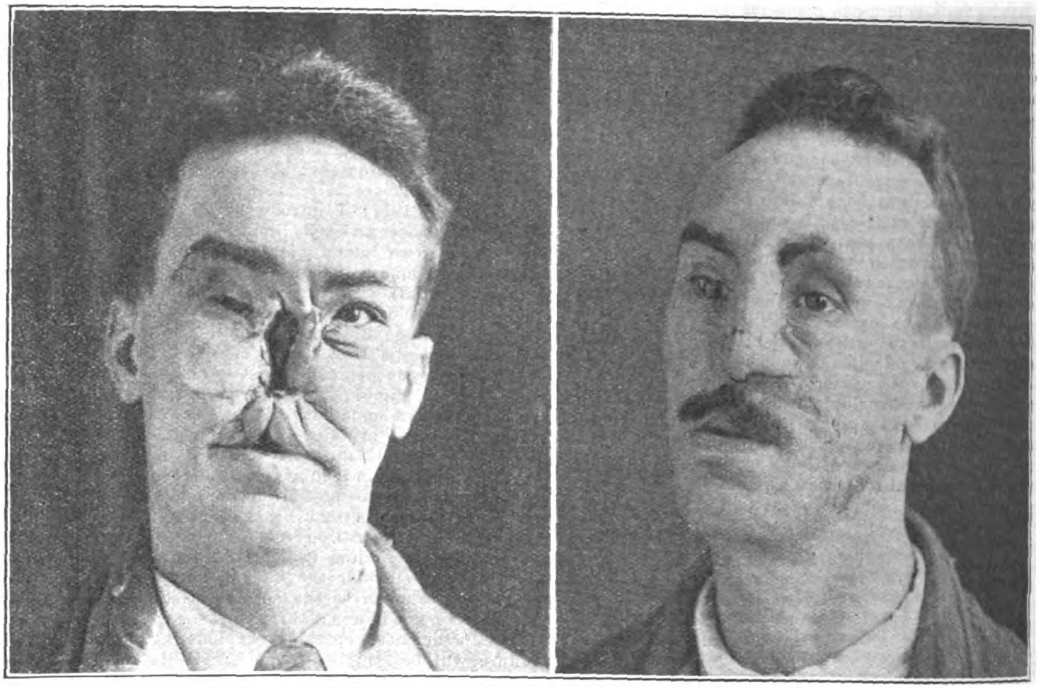
Photograph 1 (Fig. 3 A) shows the condition of the wound prior to operation. The condition of the upper lip will be noted and the position of a remnant of the right ala. Above the ala was a mass of displaced nasal bone which I removed.

Photograph 2 (Fig. 3 B) shows the ala now in the middle line. The new thick upper lip was formed by swinging a mass of tissue over towards the left side. This photograph also shows a prominent turbinate bone which had been advanced by Lieutenant Hett. The reduced area of skin opening will be noted, as also the established air passages.

Some Points in Treatment.

There are certain general matters and points of treatment to which I will now refer.

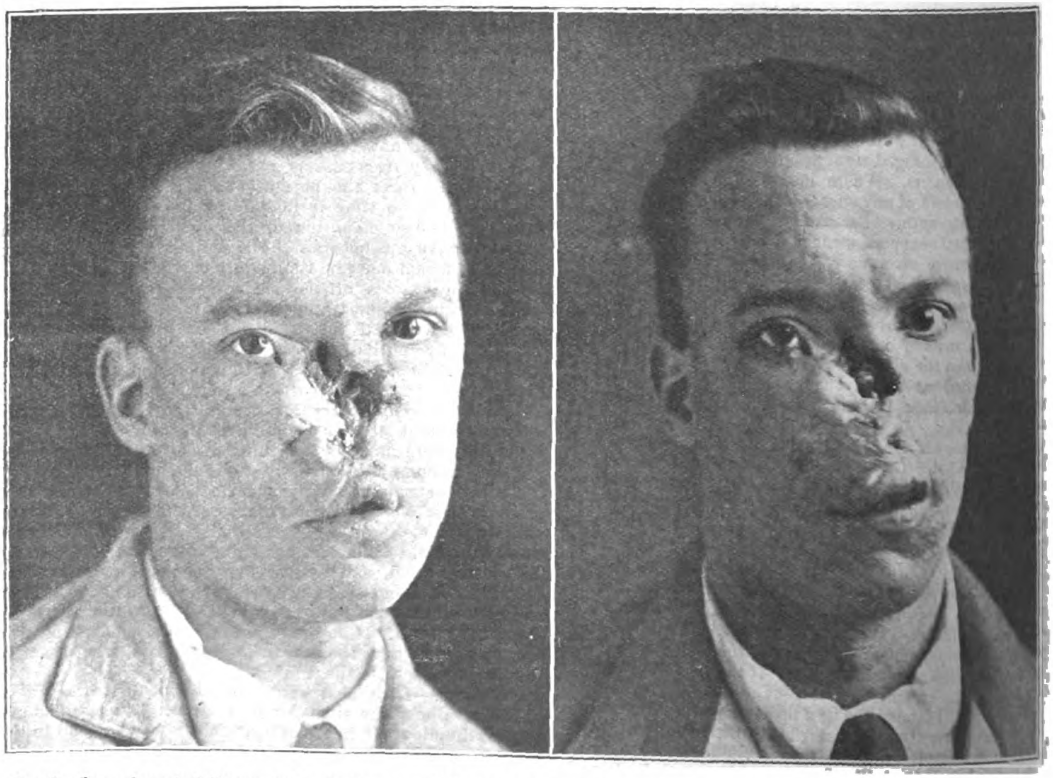
Preliminary treatment of patients.—In the first place, it is essential to get the patient as fit in general health as possible, and no time is lost by paying the most minute attention to the condition of the surrounding parts. The next all-important question is the establishment of the nasal passages, which must be thoroughly carried out.



Common sources of trouble are suppurating lacrymal sacs, antrums, sequestra, portions of nasal bones embedded in the cheeks, and the condition of the patient's teeth. This possibly entails several preliminary operations.

Removal of cartilage —Either the operating surgeon should first remove the costal cartilage (eighth) left or right, and close up the wound before proceeding to the head work, or an independent surgeon should do this part. But to avoid infection there must be no going back for further cartilage without a complete clean-up and change of everything, including instruments. The theatre sister must be also carefully watched. By failure to carry out the above régime very strictly I alone am able to account for one or two septic chest wounds. It is our principle to secure very carefully the chest wound with four or five deep silkworm mattress sutures and a long blanket horsehair upon the edge. There is, however, one caution to be added. Watch very carefully the chest wound. If undue tenderness or rise of temperature occurs, at once take the precaution to remove a suture. This may at once localise the trouble.

Dressings.—Like most surgeons, I look upon dressings as of little value other than for protection. The patient may put his hand up if not most carefully watched, and in this country, where the importance of the value of properly fly-proof wards is not fully recognised, infection may readily



[1] THE LANCET, 1917, ii., 644.

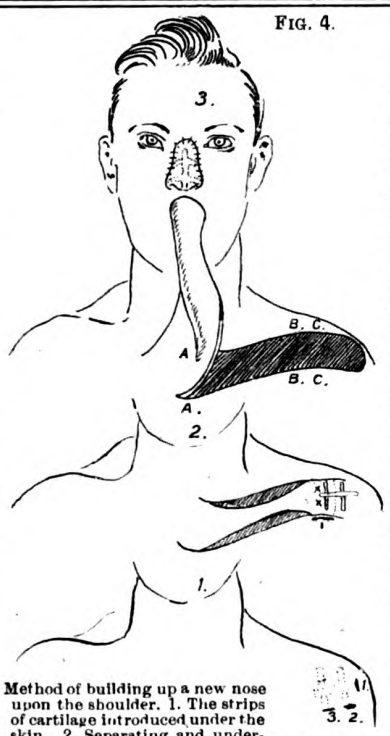
FIG. 2 A. FIG. 2 B.

Case 1.—Total loss of nose, right eye, and middle portion of lip. Reconstruction of the nose by means of (1) a small forehead flap, and (2) alar flaps *rom* the cheeks. Formation of a new lip. Introduction of cartilage sphere into eye socket.

FIG. 3 A. FIG. 3 B.

Case 2.—Loss of most of the nose with displacement of the right ala, and disfigure nent of upper lip. The new thick upper lip has been formed by swinging a mass of tissue over to the left side. The turbinate bone has been advanced. The nose will be reconstructed by a shoulder flap with long pedicle (Cf. Fig. 4).

follow from this cause. For this reason only I use ambrine wax with an addition of 50 per cent. paraffin, and sometimes also a light gauze dressing.



Sutures.—This question I have fully dealt with recently in THE LANCET (1917, ii., 347), and to this article I must refer my readers.

Subsequent treatment.—Irrespective of the few minor operations which may be necessary to complete the case, the question of mechanical treatment arises. Can the nose be straightened or the skin condition improved by any method of pressure? I have given this question considerable attention, and the conclusion I have arrived at is that mechanical pressure is useless. A puffy condition of the skin may be so compressed that for an hour or so after the removal of the appliance a satisfactory appearance is maintained, but subsequently the former condition supervenes. Massage I look upon as of the greatest value.

Lastly, let me say that I consider a complete loss of nose one in which the soft parts and bony structures up to the frontal process are absent. Every other so-called total loss of nose must be discounted. As the result is proportionate to that which is left—for instance, where the nasal bones are merely driven in and depressed—the problem is much simplified. Where one or both alæ are present also an advantage may be gained by their use.

In conclusion, I must apologise for bringing two cases forward which are incomplete, but my return to South Africa compels me either to do so or delay for a considerable period any publication. Current work, however, at the present time, whether successful or otherwise, seems to me so important that hardly any excuse would appear to be necessary.

FIG. 4.

Method of building up a new nose upon the shoulder. 1. The strips of cartilage introduced under the skin. 2 Separating and undercutting the pedicle, and sewing it together tube-wise. 3. The flap in position.

Nature's Plastic Surgery.

There can be no wish on the part of the profession in general or the plastic surgeon in particular, either intentionally or unintentionally, to magnify or minimise the value of work done. The plastic surgeon is no further responsible for the above results than that he has exercised his up-to-date knowledge of the treatment of jaw wounds.

The man who in this stage deserves all the credit which may be bestowed upon him is the dental surgeon, who by his ingenuity and skill holds the fragments of the jaws together in good articulation. The point of interest to all surgeons when examining critically the work of the plastic surgeon is to discard the first photograph, but to examine carefully the one depicting the result of Nature's efforts prior to operation. Fig. 5 shows such a result of Nature's plastic surgery. No treatment was applied between the periods at which the two photographs were taken, with the exception of a dressing with No. 7 paraffin—the War Office substitute for ambrine—as suggested by Major Gillies.

To give a photograph of the original condition of the patient and to miss out this photograph is, from my point of view, more than misleading. To the experienced plastic surgeon some of the largest facial wounds which appear sensational before and behind the camera present few difficulties by the time Nature has completed her part. The plastic surgeon only wishes for credit for his subsequent work.

THE USE OF THE TURBINALS AND THE SEPTUM IN THE REPAIR OF INJURIES AND DEFECTS OF THE WALL OF THE NASAL CAVITY.

BY G. SECCOMBE HETT, M.B. LOND., F.R.C.S. ENG.,
LIEUTENANT, R.A.M.C.; SURGEON TO QUEEN'S HOSPITAL FOR FACIAL INJURIES, SIDCUP, ETC.

THE middle and inferior turbinals and also the septum nasi have proved very useful in the author's experience for the repair of damage to the nose due to war injuries. The inferior turbinals have also been found to be excellent for the repair of wounds in the floor of the nose causing perforations through the palate.

In the experience of every rhinologist adhesions between the septum and the turbinals are very ready to form if there is an abrasion of contiguous surfaces in the nasal cavity. Even without actual contact, blood clot seems able to become organised and promote an adhesion between adjacent abraded mucous membranes. Such adhesions form only too readily after intranasal operations, and it is difficult to prevent them re-forming when once established. Furthermore, the vitality of the turbinals is great owing to their vascularity, and they are able to persist and to form new attachments, even when surrounded with muco-pus.

Perforations of the Floor of the Nose.

Early in 1916, in a case of gunshot wound of the nose with perforation of the anterior portion of the hard palate, I detached the anterior end of the left inferior turbinal and pushed it down into the cavity, which it filled and formed a sound watertight plug. This was done at the late Lord Lucas's Hospital for Soldiers at Wrest Park. During the same year Major Gillies independently made use of the turbinals for the repair of the walls of the nose.

Technique.—The attachment of the inferior turbinal is cut through for the requisite distance and, the margin of the perforation having been freshened, the turbinal is pushed backwards and into the perforation. A circular cut is made in the mucous membrane of the turbinal where it protrudes into the palate, and it is then stitched in position by several horsehair sutures, the raw areas of turbinal and palate being co-apted.

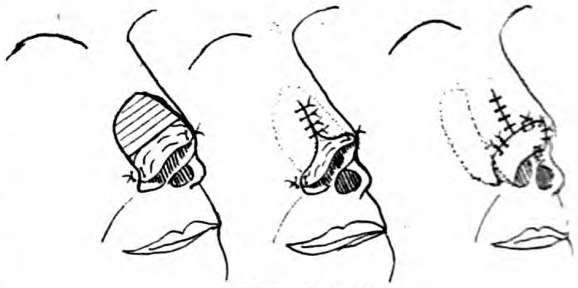
When firmly attached to the palate the turbinal can be severed entirely from its connexion in the nose. This latter procedure may be necessary from two points of view, one being to prevent the possibility of nasal obstruction, the other being that if, although adherent to the palate, the perforation is not entirely obliterated, the intranasal portion of the turbinal can be pushed further into the perforation, so as completely to fill the latter.

In cases where the perforation was at the junction of hard and soft palate, I have first detached the posterior end of the turbinal and fixed this to the posterior margin of the perforation, and subsequently when the blood supply of this attachment was established I then detached the anterior portion and pushed the turbinal bodily backwards and downwards into the perforation so as to close it. (See Diagram A.) Lastly, a free turbinal graft may be taken and used to fill up the gap, but I do not think this method is as safe as the former.

Destruction of the Ala.

In one case (Case 1), where the right ala nasi had been destroyed, I employed the free turbinal graft to form a support for the new ala. In this case the anterior portion of the inferior turbinal had been destroyed as well as the ala. I therefore removed the anterior half of the left inferior turbinal and attached it anteriorly to the septum and posteriorly to the junction of the nasal floor and outer wall of the nose. It formed attachments and lived. A fortnight afterwards I turned a skin flap from the cheek and covered it over, having previously removed the mucous membrane from its other side. This combination formed a good ala, although a somewhat rigid one. (See Case 1 and diagrams.)

FIG. 1A.



Case 1.—Before operation.

FIG. 1B.

Case 1.—After operation.

FIG. 1C.

Diagrams of Case 1.

Wounds of the Bridge.

In cases of loss of the upper part of the bridge of the nose the middle turbinals are useful in filling up the hole and also in combination with the septum they can be made to form a support for the skin flap which is subsequently brought down to cover over the gap. They also have the advantage that the mucous membrane of their deep side can be left and thus form a mucous membrane lining as well as a support for the overlying skin flap.

Technique.—The middle turbinal is detached posteriorly by cutting through its line of attachment with a saw or a spokeshave. The cut stops within ¼ inch of the anterior end. The turbinal is then swung round so that its posterior end protrudes through the opening in the nose. The turbinal is now laid transversely across the gap, resting on the remains of the septum if present, or joined to the middle turbinal of the opposite side which has been treated similarly. In this latter case the posterior end of both turbinals are rawed and sewn together, so as to form a pent-house.

If the gap is more extensive the inferior turbinals may be similarly treated so as to form a double pent-house, all four turbinals being attached together after their adjacent surfaces have been rawed. This double pent-house forms a solid mucous-lined support for the subsequent plastic operation, and if, as is often the case, further prominence is required, it is no bar to the use of a rib-cartilage graft in the skin flap, which is subsequently brought down. (Diagram B.) In cases where a portion of the septum has been destroyed in the above injuries, a turbinal may be superimposed upon it, so as to restore the partition. (See Case 2.)

Total Loss of Nose.

As mentioned in the section on palatal perforations, a turbinal may be first semi-detached and its posterior made to form a new attachment, and subsequently its anterior end may be cut free and advanced to a new position. This was found useful in a case of destruction of the whole nose with great loss of tissue on the left side due to destruction of the nasal process of the left superior maxilla.

In this case the middle turbinals were twisted forward as previously described. The remains of the septum were partly detached by a cut passing horizontally backwards along the floor of the nose, which then curved upward towards the roof. A pear-shaped piece of septum was thus obtained attached by a pedicle above. It was turned sideways and stitched to the left middle turbinal which was twisted downwards. The lower end of the left middle turbinal was attached to a piece of turbinal below, which had previously been brought over from the right side. The posterior end of the right middle turbinal was attached to the right (originally anterior) margin of the septum. Subsequently the anterior end of the right middle turbinal was detached and brought down to the floor of the nose to the left of the middle line.

FIG. 2A.

Case 2.—After operation; first stage.

This mass of turbinals and septum forms a very solid support and covering for the cavity and has helped materially to fill up the large area of the wound (4 inches across at its widest part). The patient is now able to blow his nose for the first time since receiving his wound. (See Case 3 and diagrams B and C.) In this case the septum was turned laterally to cover over the greatest possible space. In other cases the septum flap has been cut to give support and prominence to the bridge or to support the columella by the incisions. (See diagrams C 1 and C 2.)

FIG. 2B.

Case 2.—Before operation.

FIG. 3A.

Case 3.—Before operation.

In one case where the septum had been mainly destroyed, the maxillary crest together with the remains of the septum was swung forwards and upwards from its base and attached to the anterior end of the right inferior turbinal — the latter was detached posteriorly and its posterior end swung up and attached to the under side of the remains of the nasal bone. Thus a continuous support, consisting of maxillary crest, cartilage, and some of the turbinal covered with mucous membrane, was obtained which was firm enough to hold up the bridge of the nose. (See Case 4 and diagrams.)

DIAGRAM B.

To illustrate the method of advancement of the middle and inferior turbinals.

DIAGRAM A.

To illustrate the use of the anterior and posterior ends of the inferior turbinal to fill up traumatic perforations of the floor of the nose.

Loss of Nasal Supports.

In a case of perforating wound of the nose in which the external wound had closed, there was depression of the bridge with undue prominence of the tip together with nasal obstruction. I did a submucous resection, removing most of the bowsprit so as to depress the tip. The removed piece of cartilage was divided into three equal quadrilateral pieces. The skin over the upper part of the bridge was separated by a tenotomy knife and the three pieces of cartilage were inserted superimposed to do away with the depression. (See Case 5.)

In a similar case (L. B., Brook-street), after closing a hole in the upper part of the bridge by one frontal and two lateral flaps, the patient was still left with the same deformity as in the preceding case. In this case I subsequently did a submucous resection and by means of a tenotomy knife introduced between the flaps, was able to free a passage up to the skin of the bridge. The septum was then replaced and pushed up under the skin of the bridge. This was possible owing to destruction of the nasal bones. It improved the profile considerably. (See Case 5.)

FIG. 2C.

Case 2.—Before operation.

I do not intend to suggest that this use of the septal cartilage will replace the use of costal cartilage as a means of rebuilding the bridge of the nose in cases of rhinoplasty. Where a nose-flap from the forehead or chest is required for the formation of the whole or of the greater part of the nose it is obviously not applicable, as in such cases a rib cartilage graft in the flap is necessary. Again, in many cases of partial loss of the nose where the above measure is unnecessary, there is often not sufficient septal cartilage available and a subcutaneous rib graft on the diving-board principle frequently gives the best results.

Heterogeneous Septal Cartilage Grafts.

In certain cases the alæ and tip of the nose sink in owing to destruction of the septal cartilage, while the nasal bones and lateral support of the nose remain. This may be seen in cases of forcible blows on the nose with subsequent suppurating hæmatomata of the septum. Where the soft tissues of the septum remain intact it is possible to introduce a septal cartilage removed from a case of submucous resection and to insert it into the place of the one destroyed, and so reproduce the proper contour of the tip.

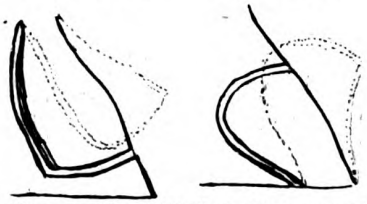


FIG. 3B.

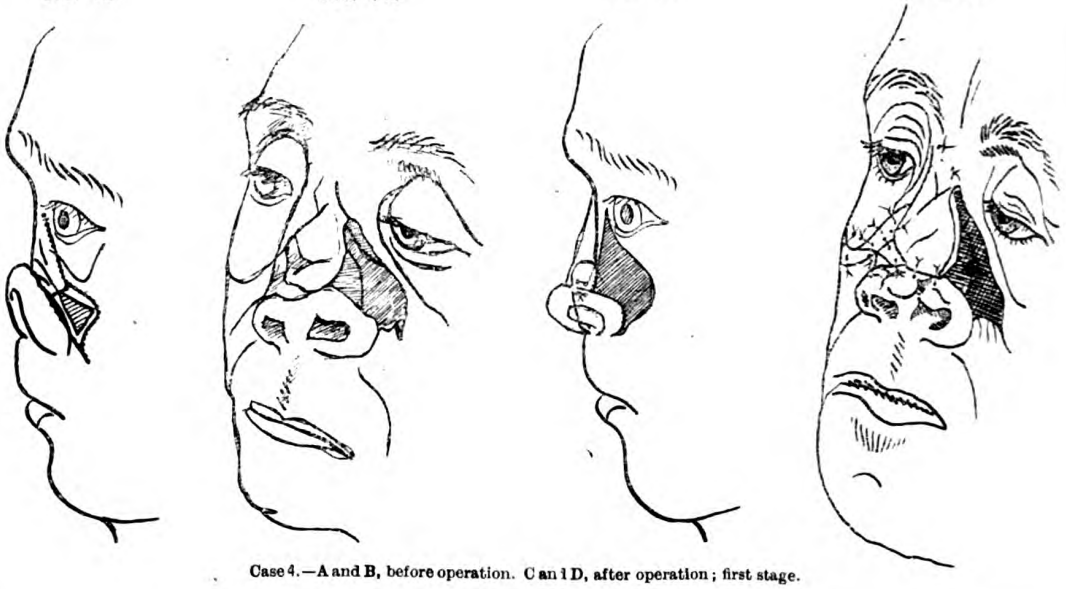
Case 3.—After operation; first stage.



An incision is made through the columella and carried between the two sides of the remaining fibrous septum. The thumb and finger placed in the vestibule guide the knife, and the incision is carried back to the bony septum and up to the central ridge of the nose, just underneath the skin. Great care has to be taken, as, of course, a perforation will spell failure, and there is no chance of separating the sides of the septum except by a knife. The free heterogeneous cartilage is then inserted, the incision in the columella sutured, and the case treated as one of submucous resection.

DIAGRAM C 1. DIAGRAM C 2.

Diagrams C 1 and C 2, illustrating upper and lower septal swings.

FIG. 4 A. FIG. 4 B. FIG. 4 C. FIG. 4 D.

Case 4.—A and B, before operation. C and D, after operation; first stage.

My experience of heterogeneous septal cartilage grafts is not yet sufficient to make a statement of their success. Instead of using a heterogeneous graft to reproduce a septum which has been destroyed, a new septum may be formed from the patient's costal cartilage and introduced in the manner described above. I used this with good cosmetic result in Case 7 (see notes of case).

The Use of the Septal Swing.

Besides the use of the septal cartilage in bringing up the prominence of the bridge, by taking it out by submucous resection and placing it under the skin of the nose, as was done in Cases 5 and 6, there are two other methods by which it may be made useful. This is by the method of septal swing, either upwards, downwards, or laterally. Diagrams C 1 and C 2 illustrate this.

FIG. 5 A.

Case 5.—Before operation.

In the case of the upward swing the septum is cut backwards along the floor at the junction of the maxillary crest. The cut is then continued upwards towards the roof of the nose and the septal flap, including cartilage and mucous membrane, is swung forwards. Remaining attached by a pedicle above, it is retained in position by advancing the two middle turbinals, so that a pent-house supports the partition. This is useful for producing a prominence due to loss of tissue of the upper part of the bridge. (See Case 3.)

The reverse of this is done for the lower septal swing. The cut is made backwards, downwards, and forwards, and the septal flap tilted forwards, remaining attached to the floor of the nose. This is useful in cases of the pug-nose type, where the alæ sink in, so that the external nares approximate more to the vertical than to the horizontal position. (See Cases 4 and 7.)

Lastly, in loss of one side of the nose the septum may be swung outwards by means of a horizontal cut along the floor of the nose and two parallel cuts carried at right angles to this up to the bridge. (See Case 1, Fig. 1 C.)

Conclusions.

As a result of my attempt at building up the nose from the inside I have come to the following conclusions:—

1. The turbinals and the septum are capable of being advanced into new positions to form fresh attachments and continue to live.

2. The advancement of the turbinals is a useful procedure in the cases of loss of the whole or part of the nose.

3. The upper septal swing is useful as an aid for supporting the new bridge of the nose.

4. The lower septal swing is often required in the pug-nose type. In these cases the septum may be sometimes swung forwards and downwards with the tip of the nose and alæ attached, and help to retain the latter in their new position. The lateral septal swing may be used to form a support for the side of the nose.

5. The septal cartilage after removal by submucous resection may be used as a free autogenous graft for increasing the prominence of the sunken bridge or for a nasal support. Heterogeneous septal cartilage graft may be used in the same way as an autogenous cartilage graft to restore the contour of a sunken nose, to elevate a tip or raise a bridge by using it to form a new septum nasi.

FIG. 5 B.

Case 5.—After operation.

Illustrative Cases.

CASE 1.—Corporal H——, patient at the Hospital for Facial Injuries, Brook-street. The lower half of the right side of the nose had been destroyed, including the right ala, by gunshot wound. (Fig. 1 A.) The mucous membrane of the right half of the cartilaginous septum was separated. It was incised by three cuts, leaving it attached below as in the

FIG. 6A.

Case 6.—Before operation.

FIG. 6B.

Case 6.—Before operation.

FIG. 7A.

Case 7.—Before operation.

diagram. The cartilage with its left half of mucous membrane was then cut through, leaving it attached above. The cartilage was then swung over and attached to the edges of the wound which had been previously freshened. The right inferior turbinal had been partially destroyed. The anterior half of the left inferior turbinal was removed and placed across the gap below the septum in the position of the ala. It was attached to the tip of the nose and to the junction of floor and outer wall of the nose. The cartilage was covered by undercutting and advancing skin over it. A fortnight later a cheek flap was turned down and attached over the turbinal from which the mucous membrane of the outer side had been removed. The side of the nose had therefore both a mucous lining and a support. The case did well, and the patient can breathe well through the nose. (Fig. 1 B.)

CASE 2.—Private H——, at the Queen's Hospital, Frognal, Sidcup. Gunshot wound of left, and bridge of nose. (Fig. 2A and B.) The left eye had been removed, the upper half of the nose had been destroyed, and there was nasal obstruction.

First operation.—Removal of adhesions between both middle turbinals and septum. Removal of sequestrum from the neighbourhood of the opening of the right frontal sinus.

Second operation.—The right middle turbinal was detached posteriorly, its anterior attachment being left. The turbinal was swung forwards and downwards, and superimposed upon the septum to which it was attached. It grew in this position, thus forming a support for the skin flap, which will shortly be brought down to cover the gap.

CASE 3.—Lieutenant S——, the Queen's Hospital, Frognal. In this case the whole nose was destroyed by gunshot wound. In addition the wound extended to the left with destruction of the nasal process of the superior maxilla. Major Gillies had previously placed a costal cartilage graft on the forehead and a portion of the left inferior turbinal had been advanced. (Fig. 3A.) There was a very wide gap in the face and it was thought advisable to try to cover this up to some extent by turbinal and septal advancement.

The right and left middle turbinals were swung downwards and forwards. The upper septal swing was used, but instead of supporting the swung-forward septum in the usual pent-house manner, the septum was turned sidewards, so as to cover over as much space laterally as possible, and the turbinals attached as shown in the diagram. The mass of tissue has lived and hypertrophied and now forms a hypertrophied and raspberry-like mass very nearly filling up the cavity. (Fig. 3B.) This patient will soon be ready for bringing down the new nose. He can now for the first time since the injury blow his nose.

CASE 4.—Private C——. Wounded May 2nd, 1917. Admitted (from a General Hospital, France) Sept. 23rd. Condition (Oct. 3rd): The bridge of nose was flattened and sunken in, due to loss of nasal bones and the majority of the nasal septum. The flattening was more marked on the left side owing to the destruction of the nasal process of the maxilla. There was an opening into the nose in this position. The soft tissues of the bridge of the nose were reduced to a mass of scar tissue. The alæ had sunken in so that their lumen was vertical.

Operation.—Oct. 3rd; Lieutenant Hett. A transverse incision was made just above the alæ, and these were turned down into their normal position. A piece of maxillary crest and remains of septum was turned upwards and forwards from the floor of the nose. This was attached to the anterior end of the right inferior turbinal. The inferior turbinal was then turned upwards and its posterior end attached to tissues at the base of the nose. This was so arranged that the turbinal and septum graft formed a continuous bony and cartilage rod covered with mucous membrane, which was found to form a sufficiently firm support for the bridge. A cheek flap was cut which, together with a flap of healthy skin from the base of the nose, was of sufficient size to be joined to the right ala and form the right half of the nose. The left half of the nose was left widely open for drainage, as the left maxillary antrum was found to be unhealthy. It is intended to turn in the scar tissue of the left cheek and to cover it with a forehead flap containing cartilage if necessary.

FIG. 8 A.

Case 8.

FIG. 8 B.

Fig. 8 B (Case 8).—Before operation; first stage.

FIG. 8 C.

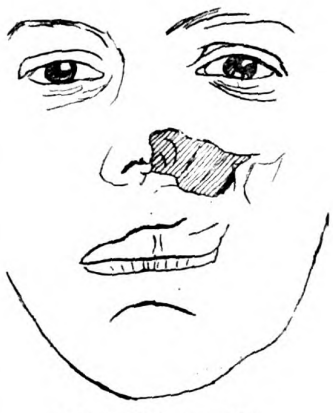
Fig. 8 C (Case 8).—After operation; first stage.

CASE 8.—Private R. C——, aged 19. Admitted Sept. 3rd, 1917. Destruction of the greater part of bony superstructure of nose, including greater part of the nasal bones and the nasal process of the superior maxilla. The alæ of the nose were present. There was a hole about the size of a threepenny-piece above the ala. The alæ had the usual vertical displacement (pug-nose type).

Operation.—Oct. 12th; Lieutenant Hett. First stage of restoration of bridge. Transverse cut above the alæ. The alæ brought down into horizontal position. The margins of the perforation cut away and the soft tissues of the nose turned over to the left. The remainder of the septum was swung forward and stitched to the underlying soft parts, so that the prominence of the bridge was to some extent restored. A large opening was left in right half of the nose. (Fig. 8 A, 8 B, 8 C.)

CASE 9.—Rifleman T. H——, aged 32. Wounded May 27th, 1917. Admitted July 11th. Transferred to Queen's Hospital August 21st. Shrapnel wound left side of face. Left half of nose absent. Antrum open on face. Opening from floor of antrum through gingivo-labial fold. (Fig. 9 A.)

Operation.—Sept. 27th; Lieutenant Hett. Opening between the antral cavity and the mouth was closed by raising the antral mucous membrane round the opening and closing the edges by silkworm-gut sutures. The upper lip was everted, and the mucous membrane of the alveolus and inner surface of upper lip was also sutured together by horsehair sutures. The left middle turbinal was detached posteriorly, twisted forwards, and its posterior end attached to the anterior portion of the floor of the nose so as to form a support for a subsequent plastic operation on the nose. The right ala nasi was adherent to the septum by adhesions. The ala was partly detached below and the adhesions removed and a tube inserted into the right nasal cavity, thus establishing the patency of the right nasal passage.



CASE 5.—This patient had sustained a gunshot wound which penetrated the base of the nose and necessitated the removal of the right eye. The external wound of the nose had healed so that there was no perforation at the time of examination. There was considerable sinking in of the upper part of the bridge. This caused an appearance of undue prominence of the lip and produces the typical bird-beak deformity. (Fig 5 A.)

Submucous resection of the septum was done and several intranasal adhesions cleared. The purpose of the operation was two fold: (1) to remove the nasal obstruction; (2) to obtain a septal cartilage graft. After its removal the septal cartilage was divided into three equal quadrilateral parts. These were inserted superimposed under the skin of the upper part of the bridge, through an opening made by a tenotomy knife. The submucous resection was carried as nearly as possible to the tip of the nose so as to try to depress the latter. (Fig. 5 B.)

CASE 6.—Private S——, a patient at the Hospital for Facial Injuries, Brook-street, was admitted with a gunshot wound through the upper part of the bridge of his nose. There was an opening into the nasal cavity in this situation. (Figs. 6 A and B.) When the wound was clean a flap of scar tissue was turned across the opening so as to cover it up. A skin flap was turned up from the root of the nose and by undercutting and prolonging incisions in the line of the eyebrows a sufficient length of skin was obtained to cover over the gap and be sutured to the lower margin of the wound which had been previously freshened. Two lateral flaps were cut and were stitched to the margins of the median flap.

A fortnight later a submucous resection of the septum was performed and the cartilage removed. Some adhesions in the upper part of the nose were cleared away. A tenotomy knife was introduced between the submucous resection flaps and carried up to the bridge of the nose just underneath the skin. The septal cartilage was then reintroduced, but with its long horizontal axis vertical. This was done in order to give greater prominence to the bridge and to prevent flattening of the nose.

FIG. 9 A.

Case 9.—Before operation.

FIG. 9 B.

Case 9.—After operation; first stage.

CASE 7.—Private C——. This patient received damage to the face while serving in France by a kick from a horse. As a result of this the septal support for the nose sloughed out and also some of the lateral support. The nasal bones remained. As a result of the injury, the nose drooped and fell in from the middle of the bridge to the tip, causing a marked prize-fighter type of face. (Fig. 7 A). It was found on examination that the whole of the septal cartilage and part of the vomer were missing and the soft parts of the septum had healed and were intact.

Operation.—An incision was made down the mid-line of the columella from the tip of the nose down to the junction of the columella with the upper lip. This was deepened by a short tenotomy knife and the soft tissues of the septum were separated backwards until the remains of the vomer were met with. The division was continued upwards and forwards just under the skin of the bridge and tip. The two sides were separated also down to the floor of the nose in the same manner. By proceeding carefully with blunt and sharp-sided tenotomes aided by inspection of the inside of the nose, it was found possible to complete the separation without making a perforation into the nasal cavity.

Meanwhile Captain Aymard had exposed the eighth costal cartilage on the right side. He removed a quadrilateral piece of cartilage rather larger than the normal cartilage of the septum and about the same thickness. I then cut this into shape so that it fitted tightly between the septal flaps. The usual submucous resection plugs were then inserted and kept for 24 hours. Fig. 7 B shows the condition after operation.

Addendum on the Use of Cartilage Grafts.

Since writing the above I have experimented further as regards the making of a new septum nasi from an autogenous costal cartilage graft. This has given very good results in reproducing the contour of a sunken nose. It is only applicable where soft tissues and mucous membrane of the septum remain. The technique employed is the same as that quoted in Case 7. I have also employed this method in a modified way to support a columella and to make a new nasal spine where the latter was required to restore the contour at the junction of the upper lip and nose. The reproduction of the septal support in making a new nose is, in my opinion, of great importance in order to produce a natural appearance and to prevent subsequent falling in of the organ. In cases where both the soft parts and cartilage of the septum are destroyed the following method is under trial:—

The mucous membrane of the floor of the nose is raised with an elevator and two flat pieces of cartilage are inserted under it. After an interval they are raised with their covering of mucous membrane, but their anterior attendants are left, they are then rotated forwards, their raw surfaces are coapted, and their free ends are attached to the under surface of the new nose, which has been brought down from the forehead.

This method is designed to produce prominence and prevent subsequent falling in of the nose.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Scopolamine-Morphine Narcosis in Child-birth (Twilight Sleep).

A MEETING of this section was held on Dec. 6th, Captain G. F. BLACKER, the President, being in the chair.

The discussion was opened by the reading of the papers forming the report of the committee appointed to investigate the effects of scopolamine-morphine narcosis. The observations were carried out independently. A standard solution of scopolamine was employed, the initial dose being morphia gr. ¼, scopolamine gr. 1/150. Subsequent doses consisted of scopolamine gr. 1/450. The patient was isolated during labour, and, as far as possible, precautions were taken to avoid sensory impulses. The cases were selected by the officer in charge of the ward, and the patients were preferably primiparæ in whom no complications were anticipated. Two charts were drawn up for use in the labour-room, and at each injection observations were recorded, the results of which appear in the papers. Dr. EARDLEY HOLLAND was unable to take part in the report owing to absence on active service.

Reports of the Special Committee.

Captain HERBERT WILLIAMSON read a report on 20 cases under his care at St. Bartholomew's Hospital.

Dosage.—The initial dose of morphia hydrochloride gr. 1/4 and scopolamine hydrobromide gr. 1/150 was given when the cervix was dilated sufficiently to admit a finger, and, as a rule, when the pains were recurring regularly at intervals of not less than a quarter of an hour. One hour after the administration of initial dose, scopolamine gr. 1/450 was given, and 20 minutes later an object with which the patient was not familiar was shown to her. From this point onwards the memory test alone was employed. He thought the memory test a safe guide but not absolutely a reliable one, for there were instances in which apperception was present throughout, but amnesia was complete. It was the best guide to dosage that we possessed, but demanded considerable experience and powers of close observation in the administrator. Its value was diminished by the necessity of arousing the patient each time it was applied. Two alternative tests had been suggested—Babinski's reflex and the pupillary pain reflex. These were tried in all cases but were found of little value.

Effect upon the mother: Uterine contractions.—If the pains of the first stage were good before the administration was commenced, little effect was produced; if they were weak injections of the drugs sometimes led to their entire cessation. Their experience confirmed that of Krauss, that in uterine inertia scopolamine-morphine narcosis should be avoided, for under its influence the pains become weaker and sometimes cease entirely. In the absence of uterine inertia it was found that little effect was produced upon the strength, frequency, or duration of the contractions in the first stage. The second stage was markedly prolonged, especially amongst the primiparæ, due to the lack of voluntary expulsive efforts on the part of the patient, and in three of the cases to weakening of the uterine contractions. The third stage was prolonged, but there was no severe post-partum hæmorrhage. In three cases there was a temporary relaxation of the uterus four or five hours after delivery. A high percentage (45 per cent.) of the patients were delivered artificially. This was partly accounted for by the high proportion of abnormal labours, but Captain Williamson was of opinion that some of the patients in whom forceps were applied would have delivered themselves spontaneously had not the bearing-down efforts been present, and therefore that scopolamine-morphine narcosis increased the number of instrumental deliveries.

General effects.—There was no tendency to increase of the maternal pulse-rate, and in only 1 case were the respirations affected. Thirst was complained of by almost every patient. Nausea and vomiting were present in 4 cases. Distension of the bladder with inability to pass urine, necessitating the use of the catheter, was present in 6 cases. Flushing of the face and dryness of the skin were marked, but never caused much distress. Restlessness was common during the stage of induction. *Analgesia* was marked in 12 of the patients, slight in 5, and absent in 3. No definite relation could be traced between analgesia and amnesia.

Complete amnesia was attained in 11 cases...	=	55 per cent.
Incomplete ,, ,, ,,	4 ,, ...	=	20 ,,
,, ,, ,, absent	5 ,, ...	=	25 ,,

In these the whole course of labour was remembered.

Effects upon the child: Fœtal heart.—In 16 cases the fœtal heart rate was not affected; in four there was increased frequency which might have been due to the labour itself.

Condition at birth.—Nineteen of the children were born alive. One child was stillborn, but this was not to be attributed to the scopolamine-morphine narcosis. Of the 19 born alive, 8 were born in a condition of oligopnœa, undoubtedly due to the combined action of scopolamine and morphine. Most twilight sleep babies were born in this condition, and although it appeared alarming, it was transient and need not cause anxiety. No treatment was required beyond covering up the child and keeping it warm.

History of the children after birth.—Of the 19 children born alive, all left the hospital well. In the majority there was no evidence that the scopolamine had produced any effect upon the child. There was no evidence that it was excreted in the milk, several cases having been examined.

The puerperium and period of recovery were not affected adversely by the injections. After long and trying labours the twilight sleep patients made a quicker recovery than those who had been delivered without it. Lactation was not affected unfavourably.

Captain J. S. FAIRBAIRN read a paper giving his observations on 80 cases at St. Thomas's Hospital.

The usual *dosage* was used except in a few of the later cases, when a slight modification was made, the second injection being 1/300 gr. hyoscine instead of 1/450. Cases of normal labour were preferred. Administration was begun when pains were regular at about five-minute intervals and the os about two fingers, but it was difficult to be sure of the precise moment. Of the 80 cases 60 were primiparæ and 20 multiparæ. The number of injections varied from 1 to 19, the average being 6·5. In the primiparæ the average was 7·2, and in the multiparæ 5·5. The memory test proved quite useless. The behaviour of the patient between and during the pains and the notice she took of the prick of the needle were found to be more useful, and had the great advantage of involving no additional disturbance to the patient. Their method was to begin with hourly hyoscine injections, and when the drowsiness and absence of response to the pains injections, or other manipulations indicated that the woman was fairly narcotised to omit one or more of the hourly injections. *Amnesia* was classified as "complete" when the patient remembered nothing from the time of the first injection; as "partial" when she had no clear recollection of her labour, but retained some impression of the final expulsive pains; and "absent" when she was able to recollect the events and progress of her labour.

Complete amnesia was obtained in 36 cases...	=	45 per cent.
Partial ,, ,, ,,	26 ,, ...	=	32 ,,
Amnesia was absent in	18 ,, ...	=	22·5 ,,

Analgesia was considered as complete in all those cases in which complete amnesia was obtained, partial in those cases when the patient appeared to obtain relief from the injections and was satisfied that she had had an easy labour, and absent in those cases in which she did not seem to have had any relief.

Complete analgesia was obtained in 36 cases	=	45 per cent.
Partial ,, ,, ,,	40 ,, ...	=	50 ,,
No ,, ,, ,,	4 ,, ...	=	5 ,,

General effects.—No decided influence on the maternal pulse or respiration rate was observed. In 8 cases there was slowing of the pulse-rate sufficient to be noteworthy; in only one case was quickening recorded. Sleep between the pains was present in all but 3 cases, and in 27 there were periods in the labour when the pains did not rouse the patient. Mental confusion to some degree was present in most patients in whom narcosis was well marked. Restlessness to some degree was noted in 29 cases, and in many the result was good as far as amnesia was concerned. Thirst was present in 75 per cent. of the cases, vomiting in 20 per cent., and flushing of the face in nearly 90 per cent. Dilatation of the pupils was noticed in 21 cases, or about 25 per cent. No dangerous effects on the mother were observed.

As regards the *effect on labour* itself, there was a fairly constant diminution in the strength and frequency of the contractions after the first injection, sometimes lasting an hour or two, after which the uterine contractions appeared to follow their normal development. Bearing-down efforts were present in 55, feeble in 10, and absent in 15 cases. There seemed to be a tendency to delay in the latter part of the second stage, shown by the increase in the number of forceps deliveries, which were more than three times the average ruling in the ward. The placenta was expelled spontaneously in 41 cases and was expressed after expulsion from the uterus in 39 cases. Bleeding was stated to have been greater than normal in 9 cases, or 11·25 per cent. In 4 of these cases the bleeding was described as post-partum hæmorrhage. The cases seemed to indicate a slight tendency to increase of loss in the third stage, though readily controlled, but it was impossible to ascribe the hæmorrhage as due to the narcosis alone. The condition of the patient after delivery was good throughout, and no case of shock or other dangerous symptom, except the 2 cases of post-partum bleeding, was noticed.

Effect on the child.—There were 3 cases of still-birth, two of which were due to causes quite independent of the narcotism; in the third the fœtal death was due to delay in the after-coming head. In 19 cases the child did not breathe or cry spontaneously at birth, but in 9 of these the delay was so trifling as to be scarcely worthy of notice. In 6 cases external stimulation and in 3 a hot bath were sufficient to start respiration at once. Besides these cases, in 16 there was blueness of the child for the most part trifling in character and of slight duration. Regarding pituitary extract given before birth as a contributory cause of difficulty in starting respirations, it was thought not to add appreciably to the danger to the child. There were 3 cases of *cardiac disease* in one of which the patient had been in the medical wards for several weeks owing to failure of compensation. In all these cases the partial narcosis had a beneficial effect on the patient. Out of 13 cases in which a general anæsthetic was given at the end of the second stage, complete amnesia occurred in all but one, or in 92·3 per cent. If the pain of expulsion brings the patient to consciousness the amnesic effect is lost; probably all the 26 cases classed as partial amnesia and a proportion of those in which no amnesia was obtained would have been classed as complete had the actual birth been conducted under a general anæsthetic; but given for this purpose, the second stage would no doubt be prolonged and the number of forceps deliveries increased, but the percentage of complete amnesia would probably have been raised to 90 per cent.

Captain FAIRBAIRN also read a report on 20 cases from the General Lying-in Hospital, York-road, in which the results were in general the same as those obtained at St. Thomas's Hospital.

Dr. C. HUBERT ROBERTS read a report on 67 cases observed by himself and Dr. T. G. STEVENS at Queen Charlotte's Hospital.

Amnesia.—The results were good. In 90 per cent. the pains of labour were diminished; complete amnesia was obtained in 46·2 per cent., partial in 44·7 per cent. Analgesia was complete in 32 cases, partial in 31. There were 2 failures. Indications for commencing treatment were

the character of the pains, which should be regular and strong. The size of the os could not be taken as a guide.

Dosage.—The number of injections varied. Three patients had only one injection, whilst one had ten. In all cases but one the pains were good at the time of the first injection. Indications for repetition of the hyoscin injection seemed to be the patient's general condition and the frequency of the pains. In no case was a second dose of morphia given. The memory test could not be relied on; further observations on the corneal and plantar reflexes were of minor importance in drawing conclusions. Considerable experience was required by the practitioner in the treatment of cases of twilight sleep; the same remark applied to nurses who, if left in charge of such cases, should be carefully trained in the routine beforehand, as it was more than possible that dangerous results might supervene if the giving of morphia and hyoscine were left to inexperienced persons. Any case of twilight sleep demanded the constant attendance of the doctor.

General effects on the mother.—Mental confusion, thirst, and restlessness were observed in about half the cases, but no active delirium. Labour did not seem to be prolonged after giving the first injection. Any prolongation which was noted in their series occurred before the injections were given. Out of the 67 cases there were 12 forceps deliveries, but the indications were due to obstetric complications, such as occipito-posterior positions or large head, and not due to the effects of the drug on uterine contractions. The placenta was spontaneously expelled in 65 out of the 67 cases, there being evidence that uterine contraction and retraction were not interfered with. There were two cases in which there was hæmorrhage in the third stage, one due to an adherent placenta, the other to a low-lying succenturiate placenta. These cases could not be laid to the door of the narcosis alone. The puerperium in all cases was undisturbed, nor was involution retarded.

Effects on the child.—In 53 out of 68 babies (one case of twins) breathing or crying was noted as spontaneous. In 13 cases the baby was described as blue, but in one instance only was there cause for alarm. Most of the blue babies at birth were limp but soon recovered. Hot baths and artificial respiration were only required in the minority of cases. Violent resuscitative methods for such babies were to be deprecated. Three babies died; of these, two were premature and one died of broncho-pneumonia on the sixth day. There were three cases of white asphyxia with *forceps* deliveries, due to delay from obstetric complications and not to the drugs used. A definite opinion on the effects of hyoscine and morphia on lactation could not be given owing to the short stay of patients in the hospital. Of the 64 living babies who left the hospital, 49 were breast fed and 34 had regained their birth weight during the first week.

Mr. GORDON LEY read a report on 135 cases of twilight sleep at the City of London Lying-in Hospital observed by Dr. COMYNS BERKELEY and himself.

Dosage.—Of the 135 cases reported on, 128 were primiparæ and 7 multiparæ. The first injection was given with the cervix two fingers dilated and the pains strong and regular. The dosage was that agreed upon. The second dose was given three-quarters of an hour to one hour after the first and succeeding doses at hourly intervals. The number of injections varied from 1 to 53, with an average of 13·1. Morphia was repeated in 1/6 gr. dose in 7 cases when consciousness was being gradually regained, and produced a satisfactory return to the twilight state. The memory test was applied in all cases and was found generally unsatisfactory.

General effect on mother.—Catheterisation was, as a rule, necessary during labour. Complete amnesia was produced in 47·4 per cent. of the cases; partial amnesia in 45·2 per cent. Complete analgesia was produced in 8·2 per cent.; partial analgesia was present in 22·9 per cent., excluding, in each case, those patients in whom there was complete amnesia. Thirst was present in 63 per cent. of the cases, nausea and vomiting in 24 per cent. Mental confusion was marked in 24 per cent., slight in 34 per cent. Restlessness was considerable in 25 per cent., slight in 17 per cent. Excitement was present in 35 per cent., and a small proportion of these were maniacal. Pulse and respiration were never affected. In 34 per cent. the pains appeared *sub*normal, and in 1 case there was complete suppression. The interval between the pains was in all cases normal. Bearing-down efforts were, as a rule, subnormal; they were good in 44 per cent., fair in 3 per cent., slight in 40 per cent., very slight in 3 per cent., and absent in 10 per cent.

Labour.—There was prolongation of the second stage of labour. Compared with the average percentages of the hospital, the number of forceps cases was increased; perineal tears were greatly in excess (due to the difficulty of controlling the patient with the head on the perineum), and there was an increased failure of occipito-posterior positions to undergo spontaneous rotation, attributable to the lack of bearing-down efforts which, combined with strong pains, are so important in the spontaneous rotation of these positions. The third stage was unaffected.

Effect on infant.—In some cases, especially when chloroform was given, there was a disinclination to breathe, associated with cyanosis and general limpness. Three children were still-born. In one the pregnancy was only 32 weeks advanced. In the other two death was almost certainly due to intra-uterine pressure from the drainage away of the liquor amnii. Of the children born alive the subsequent condition of 129 was satisfactory. Six died within the first 20 days of life, but in none could it be said that the treatment played any part as a cause of death. From the point of view of the practitioner, it must be remembered that the number of forceps cases is considerable, and are relatively difficult owing to the fact that the diminished bearing-down efforts fail to force the head deeply into the outlet, or fail to rotate occipito posterior positions, which therefore require manual rotation before extraction. The condition of the baby may cause grave anxiety to the inexperienced, and deaths are likely to be produced by too vigorous treatment. The constant attendance of the doctor and the absolute necessity of having a nurse skilled in this line of treatment cannot be impressed too forcibly on patient and friends. The treatment requires considerable experience both of the method itself and of midwifery, and it appears probable that it should be withheld in all cases except those in which the capacity of the patient for bearing pain is greatly below normal, and is evidenced early in labour.

Discussion.

In the discussion which followed Dr. W. A. POTTS said that he never had nausea or vomiting with his cases. He thought the restlessness might be due to overdosage with hyoscine. He always gave morphia gr. 1/4 to 1/6, and hyoscine gr. 1/200, and for subsequent doses of hyoscine gr. 1/200 at 2-hourly or longer intervals. If the patient were not under at the third dose he gave a whiff of chloroform, and in this way could make a success of any case. He usually used chloroform at the end of labour, giving the last dose at some considerable interval before the child was born, so that at that time the patient was just coming from under its effects. It was essential that the patient be given water at intervals when the labour was prolonged, and it was advisable to let her come out from the influence of the drugs and have a meal and then start the administration again. This diminished the tendency to uterine inertia. He had only had one case of post-partum hæmorrhage and that was probably due to slight capillary oozing from a small laceration of the cervix. He had not found an increased use of the forceps necessary.

Dr. W. O. GREENWOOD said that out of a series of 240 cases he had only had two complete failures. He thought that his success depended upon frequent and rigid testing of the patient. The dose could be standardised, but the patients differed in their reaction to the drugs. He had used morphia gr. 1/4, and scopolamine gr. 1/100. Only highly nervous patients needed larger doses. He thought gr. 1/450 too small a dose on the whole. He thought that if amnesia was perfect it was safe to say that there was some analgesia.

Dr. J M BRYDONE thought the method could be made an absolute and complete success from the patient's point of view. A little chloroform at the start was a great help. He had never given more than three injections. He had had no trouble with the babies. He had found the memory test unsatisfactory.

Dr. ROBERTS recapitulated the points of the paper by Dr. Stevens and himself. The method had given good results. Pain was diminished in practically 90 per cent. Administration should be begun when pains were regular and strong. The size of the os was no guide. Judgment was necessary with regard to the number of injections to be given. Repetition depended upon the condition of the patient and on the pains. Further observations were necessary to determine the value of the memory test. The corneal and plantar tests were of minor use. Training of physician and nurse was very necessary. Constant attendance on the part of the physician was needed. Prolongation of labour was not marked in their series. Warmth and quiet were all that were needed for the baby.

Lady BARRETT said that in a series of 30 hospital cases she had always given morphia gr. 1/6. Patients had rarely failed to remember objects shown, but many had amnesia with regard to labour. She had had greater success by giving small amounts of chloroform at the end of labour, so that the last few pains were not remembered. There had been no case of post-partum hæmorrhage. The only still-birth was a small premature child.

Dr. COMYNS BERKELEY said that the memory test was no good. The only danger to the child was in trying to revive it. Strict supervision was necessary.

The PRESIDENT said that the method was by no means devoid of danger. Hyoscine was a dangerous drug owing to an idiosyncrasy towards it on the part of certain people, and once given hypodermically it could not be recalled. And on top of this dangerous drug chloroform was given as a general anæsthetic. The morbidity increased with the number of forceps cases. There was an increased morbidity of the mother, an increased mortality of the mother, and increased mortality of the baby.

Captain WILLIAMSON said the method was valuable in suitable and selected cases. It should be administrated after every precaution was taken, and only by those who were competent to deal with any obstetrical emergency which might arise.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A well-attended meeting was held at the West London Hospital on Dec. 7th, Dr. A J. Rice-Oxley being in the chair. —Papers were read on (1) Methods of Detecting Simulated Deafness, by Mr. Richard Lake, and (2) Methods of Detecting Simulated Blindness, by Mr. Percy Dunn.—A discussion followed, from which it emerged that these forms of malingering were very uncommon in the British Army, as far as the experience of the members present went.

HUNTERIAN SOCIETY.

The Medical Classification of Recruits.

A MEETING of this society was held on Dec. 6th at the Royal Society of Medicine, Wimpole-street, Mr. HUGH LETT, the President, being in the chair.

Captain HALDIN DAVIS, R.A.M.C. (T.F.), opened a discussion on the Medical Classification of Recruits. He showed how the problem has changed since the beginning of the war. At first the difficulty was to prevent unfit men from getting in, while now the problem is to ensure that no useful individual may be left out. He traced the steps by which the present system of grading recruits in various categories had arisen and explained the provisions of the different Army Council instructions bearing on this subject. He ascribed most of the troubles which were made by the Recruiting Medical Boards under the War Office to two causes: First, the great rush of work, which necessitated sometimes as many as 300 recruits being examined in one day; and, secondly, to the fact that they were provided with no general instructions as to the lines upon which they were to proceed and the consideration to be paid to the different conditions they might meet with. In both these matters, Captain Davis said, the boards working under the Ministry of National Service have a great advantage: Firstly, there is unfortunately no rush of recruits at the present time, and the boards are consequently not overburdened with work; and, secondly, they are provided with an excellent handbook of instructions which the Ministry of National Service, profiting by the experience of the War Office, have issued for the benefit of their commissioners and medical staff. There was no doubt that working under these conditions the Ministry of National Service would be able to obtain far more uniform standards throughout the country and give more satisfaction to the public. Captain Davis classified the defects which diminish but do not absolutely nullify a man's military value under the following heads: (1) deficiencies of the senses; (2) defects of the heart and lungs; (3) defects of other internal organs, especially of alimentary system; (4) defects of the nervous system; and (5) defects of the locomotive system—i.e., the spine and limbs. He pointed out as regards vision that, as the standard had had to be lowered considerably, it was a question whether a man with only one eye, but that eye perfect, should not be considered as eligible for category A. As regards cardiac defects, he was of opinion that the only useful criterion of fitness was reaction to work, and that the elaborate examinations of the heart made by modern methods were extremely useful. He mentioned the practical point that young recruits whose heart muscles seemed doubtful at first often improved on training, but that elderly ones—i.e., over 33 or 34—never did. Many of the latter can stand the first few weeks, but afterwards steadily degenerate. He emphasised the importance of good digestion to the soldier. While recognising the difficulty of detecting cases of gastritis by examination, he thought it was a pity that so many crept into the Army, and was of opinion that the best thing was to get rid of them at the earliest possible moment. As regards nervous diseases, the most difficult problem is the neurasthenic, who, in Captain Davis's experience, usually ended in the cookhouse. As regards the delicate question of certificates given by private medical practitioners, he was of opinion that the correct course for the practitioner to take was to refrain entirely from giving any opinion as to the fitness or otherwise of the patient, and merely to set down the physical signs found and the medical history during the time he had attended him.

Dr. RUSSELL WELLS said that if such papers had been read in the early days of the war much difficulty in connexion with the examination of recruits would have been avoided. Since February, 1916, the recruiting medical boards of London, at the desire of the War Office, had referred to the National Hospital for Diseases of the Heart doubtful cardiac cases for examination and report. Up to the present time 10,190 cases had been reported on. The name, age, and occupation of each recruit, and a statement of how he felt, in his own words as far as possible, was recorded. A careful history of his previous diseases, habits, and subjective symptoms, such as dyspnœa, pain, palpitation, vertigo, faintness, sleeplessness, &c., was taken. This part of the examination, depending, as it did, on the man's truthfulness, though important, could not be given as much weight as the rest of the report. The urine was examined. The recruit had his pulse-rate, blood pressure, and rate of respiration taken in the recumbent position and was then made to run up and down stairs, so as to raise his body 20 feet vertical in 30 seconds; immediately afterwards the pulse-rate, blood pressure, and respiration were taken again. After resting in the recumbent position for three minutes pulse, blood pressure, and respiration were again recorded. He was then weighed and his electrocardiogram taken. After this his heart was examined by the screen with X rays, with due precautions as to centering the tube, a record being made of its size, shape, position, and transverse diameter. After this he was examined by the usual clinical methods, the observations being noted under the headings of inspection, palpation, percussion, auscultation, and the state of other organs, in so far as they related to the cardiac condition. A diagnosis was stated and a recommendation as to category made, the classification, however, properly remaining entirely in the hands of the board sending the recruit for examination. In every case the full record with a print of the electrocardiogram was sent to the board and another copy filed at the hospital. The staff of the hospital were engaged on a detailed analysis of the first 10,000 cases, with a view to ultimately publishing the results, and he felt he must not allude to their conclusions, but a few of his personal observations might be mentioned. First, in the great majority of instances the cases sent to the hospital were really doubtful ones. Taking a straightforward lesion like aortic regurgitation as a test, the fact that out of the 10,000 men under 300 presented "aortic" diastolic murmurs, many of these being difficult cases, showed how carefully the boards had eliminated well-marked instances of heart disease. Drugging with a view to disturbing the heart's action, and so avoiding military service, was, he thought, not common, and was far easier to detect than was usually supposed. He gave an amusing instance of quinine being discovered in a recruit's urine, when the man confessed that he had taken two eggcupsful of ammoniated tincture of quinine "to keep himself up." He detailed the symptoms which in his experience followed the improper use of the nitrites, cordite and the like, and pointed out how they could be distinguished from genuine disease. Most of the drugs suggested as likely to be used chiefly affect the pulse-rate; and if there was one thing more than another that had been borne in upon him in the course of this work, it was the slight importance of a rapid pulse at the time of examination. Few, he thought, realised how greatly or how easily the pulse might be accelerated; nearly all normal hearts accelerated on exercise, the increase often being as much as 20 to 25 per cent. or even more, and practically always in normal people the blood pressure rose on exercise; a rise of pulse-rate with a fall of blood pressure on exertion was the bad sign. Captain Haldin Davis had said that the soft heart of the young improved with training, but that the same sort of heart in the man of 35 broke down, and he expressed his complete agreement. The slightly anæmic indoor worker who complained of shortness of breath on exertion and had a localised systolic murmur at the apex, was a very common type; he was "the atonic heart of the indoor worker." If the heart was not notably enlarged and the arteries were healthy these men greatly benefited by training, provided it was not too rapid. On the other hand, some arterial thickening was much commoner than he at any rate was formerly aware. Frequently an examination of the little bit of the radial artery accessible to the finger revealed nothing abnormal, but if the brachial artery was felt from the elbow to the axilla, marked thickening could be detected. He had seen many cases of definite arterio-sclerosis in quite young men, and when the age of 30 was passed they increased in number. He would not enter into the debatable question as to whether those localised systolic murmurs heard from the xiphoid to the apex but not conducted out, which were frequently classified as functional, originated at the mitral or tricuspid orifices, but felt convinced that in very many cases they were due to regurgitation as the result of the lax condition of the cardiac muscle. In men over 30 it was not very uncommon to find a really large heart which seemed to lie on the diaphragm; these men were frequently fat and usually dyspnœic on slight exertion. Often no murmur could be heard, sometimes a soft localised systolic murmur at the apex could be elicited by exercise; arterial

thickening was frequently absent, and they seemed to him to constitute a distinct class worthy of investigation. The present general examination of the population for military purposes afforded a unique opportunity for medical research, and he felt that if Army medical officers would examine the men under their charge from time to time and record how those with the various slighter forms of cardiac derangement stood the fatigues of training and active service cardiology would be greatly advanced.

Dr. F DE HAVILLAND HALL suggested that the formation of a probation camp to which men of doubtful physique could be sent and kept under observation would save the country expense and the individual needless inconvenience. The majority of the men would almost certainly improve under careful training, whereas the unfit could be weeded out and returned to civil life. He thought it essential that the urine of every applicant should be tested, as men with albuminuria were unsuited for exposure to wet and cold coupled with great exertion. He was opposed to passing any man for active service with the signs of quiescent pulmonary tuberculosis, and he was of opinion that at least six months should elapse in the case of a man who had had pleurisy before he was passed.

Major DUNDAS GRANT also spoke.

Reviews and Notices of Books.

Midwifery. By Ten Teachers. Under the direction of COMYNS BERKELEY, M.A., M.D., M.C. Cantab., F.R.C.P. Lond., Obstetric and Gynæcological Surgeon to the Middlesex Hospital, &c. Edited by COMYNS BERKELEY, H. RUSSELL ANDREWS, J. S. FAIRBAIRN. With 303 original illustrations and 4 coloured plates. London: Edward Arnold. 1917. Pp. x. + 735. Price 18*s.* net.

THIS book is an interesting experiment in combined authorship. It is the result of the coöperation of ten teachers in London medical schools. According to the preface, the whole corps has acted in an editorial and revisional capacity on every chapter and section of the book, both text and illustrations. As nearly all the authors are, or have been, examiners, the book will certainly be popular among students; it will be read with interest, too, by those teachers and examiners who are not among the number of the corps. The result of this method of authorship must be largely of the nature of a compromise, and the book is an eminently safe guide to the practice of midwifery. It contains nothing very startling and nothing very novel, and therefore is well adapted for the use of the student. These very qualities, however, render it less interesting than if it were the work of an individual or contained the teaching of a single school. It is divided into five sections dealing respectively with Pregnancy, Normal and Abnormal; Labour, Normal and Abnormal; the Puerperium; the Newborn Child; and a final section dealing with the various Operative Procedures.

We notice that the authors do not accept the view that the cells of the membrana granulosa are derived from the germinal epithelium, but describe them as of stromal origin. The account of the height of the fundus of the uterus during pregnancy differs very markedly from the figure given to represent these levels. In the figure the height of the fundus of the uterus at the twelfth week is shown as about 3/5th of an inch above the symphysis pubis, instead of 2 inches as it is given in the text, and at the twenty-fourth week it is shown in the figure as at the level of the umbilicus while it is described in the text as above that level.

It is always interesting in a book of this kind to read the accounts of the treatment of some of the more important accidents of childbirth. We think it a pity that the authors should figure and describe plugging the vagina in a case of placenta prævia, as the second alternative they give is much less dangerous and so much more effective—namely, dilatation of the cervix with dilators and the immediate introduction of a de Ribes bag, or the performance of version. In the chapter on accidental hæmorrhage plugging the vagina is strongly recommended for this accident; for many years the majority of London teachers were opposed to this practice, and many of them will be surprised at so complete a *volte face*. In the diagnosis of a contracted pelvis we are told in the text to introduce the right hand into the vagina, but in the figure illustrating this procedure, to which no legend is affixed, the left hand, which is much the better hand to employ with the patient on her back, is shown in the vagina. The description of internal and external cephalic and bipolar podalic version is very short and suffers as a consequence. Nothing is said of the advantage of using sometimes the left or sometimes the right hand in the vagina or of placing the patient in some cases on her back and in other cases on one or other side and employing internally whichever hand is most suitable. The description given has the merit, for the student, of being short, but he will find it of no great use to him in the performance of a difficult version. We strongly dissent from the advice to take hold of the handles of the axis-traction forceps as the head is emerging over the perineum; this is unnecessary and even bad practice.

The method advocated of rotating the head in an unreduced occipito-posterior position is not so effective as that of seizing the head between the thumb and fingers, to which there seems no valid objection, and it is certainly most efficient. The authors adopt the terms "sluggish uterus" and "exhausted uterus" for primary and secondary inertia, because they think that the use of the term secondary might lead the reader to imagine that it was so called because it follows the primary variety. It may, however, be objected that a uterus the subject of primary inertia is not always sluggish, the contractions may occur relatively often but may be quite ineffective. The two expressions "sluggish" and "exhausted" serve as very fair descriptions of the two conditions, but we think it would be a pity if such well-known and classical terms as primary and secondary inertia were abandoned.

We have been deliberately critical, so that the authors may, if they think well, introduce modifications in the future editions which they will certainly be asked to supply. There is no intention of bringing together all the fault finding in order to depreciate a book, which is a very creditable production likely to be of great practical value. The illustrations are good and well drawn, and there is a full index.

JOURNALS.

Psychobiology. Vol. I., No. 1, July, 1917. London: Cambridge University Press; Baltimore: Williams and Wilkins Co. Bimonthly, $5 50 per year.—This is a new journal devoted to the field common to psychology and the biological sciences. The editorial staff is representative of some of the leading investigators among the university staffs of the United States, and in their opening announcement they declare their aim as the furtherance of research bearing on the interconnexion of mental and physiological functions; they welcome investigation in pharmacology, physiology, anatomy, neurology, and psychiatry in so far as it has explicit specific relation to problems of mental life. The number with which the venture opens contains several papers, reference to the titles of which will give the reader sufficient indication of the scope of the journal. Dr. S. I. Franz and Dr. K. S. Lashley, of the psychological laboratory of Johns Hopkins Hospital, record experiments on the retention of habits by the rat after destruction of the frontal portion of the cerebrum; Dr. D. I. Macht and Dr. S. Isaacs have a paper on the action of some opium alkaloids on the psychological reaction-time; Dr. R. Ogden and Dr. S. I. Franz describe a series of investigations on the recovery from experimentally produced hemiplegia in apes. We congratulate the editors on this inauguration of an attempt to bring physiology and psychology closer; it is in a way, a protest and a reaction from the teaching of a school of psychology which lives in a world of concepts, ignoring the fundamental basis of its own science.

Veterinary Review. Edited by O. CHARNOCK BRADLEY, M.D., D.Sc., M.R.C.V.S. Vol. I., No. 4. November, 1917. Price 3*s.* 6*d.*—Professor Bradley, the principal of the Royal (Dick) Veterinary College, Edinburgh, in the *Veterinary Review*, gives to the professions of human and veterinary medicine a résumé of all the latest work done in comparative science at home and abroad. Abstracts have been made from every branch, including anatomy, hygiene and preventive medicine, parasitology, surgery, serology and immunology, infectious diseases, toxicology, and teratology. The worker who wishes at a glance to know the latest which has been done, after consulting this Review may be able to put his finger on the full details which he desires without searching through a lot of tedious literature. The November number is well up to the high standard of its predecessors.

CUPRASE

For the Medical Treatment of CANCER.

Clinical facts carry greater weight than theoretical deductions. Doctors of repute in various countries give cases of great variety. In all of these **pain has been eliminated,** and in a good percentage cures are claimed, with **no** undesirable effects. It should be remarked that all or nearly all the observations refer to inoperable cases in which the prognosis was unfavourable at an early date. It is needless to emphasize the practical importance of a preparation capable of yielding such results, even relative, in the worst stages of a disease which has always been regarded as absolutely resisting the action of all internal remedies.

Nothing has been found which can compare with the effects produced by means of Cuprase.

Its easy application (intramuscular injections) places it within the reach of all practitioners. **It is not toxic.**

Cuprase is a colloidal Copper hydroxide obtained by the reduction of Salts of Copper in the presence of Albumosic Acid.

Disappearance of the **Pain.**

Return of Sleep.

Increase of Appetite,

Colour and **Strength.**

WARWICKSHIRE, July 1st, 1917.

DEAR SIRS,—Will you please send me another box of Cuprase ampoules. The previous lot effected a most remarkable cure in an elderly lady suffering from cervical cancer — the cauliflower-like growth has disappeared with its offensive discharge.

This case was given three months' life by a Specialist, being inoperable.

Yours faithfully,
(Signed)
G—— B——, M.R.C.S., L.R.C.P.

Dr. GAUBE DU GERS' Cuprase is administered in intramuscular injections made *very slowly* in the gluteal region, with a needle of about 0·03 cm. at the rate of an ampoule every four days, which should be continued in the same manner as long as necessary. These punctures are not generally painful and do not produce any local reaction.

LONDON: SATURDAY, DECEMBER 15, 1917.

The Repair of the Nose and Jaws.

THE problems presented to surgery in the present war, though mostly having a counterpart in lesions met with, more or less frequently, in civil practice, differ from them generally in the extent of the lesions which have to be treated, and also in the very large number of analogous cases of different groups with which the surgeon has to deal. It is therefore not surprising that expedients have been devised and methods have been invented to which the experience of previous civil practice and earlier wars had not given rise. That is only to say that intensive study has evolved pertinent remedy. In THE LANCET of last week papers by Major H. D. GILLIES and Captain KELSEY FRY appeared which described the new departures in surgery resulting from the special care of cases of severe facial injury at the Queen's Hospital, Sidcup, and this week two more papers belonging to the same category are published, one by Captain J. L. AYMARD and one by Lieutenant G. SECCOMBE HETT. Every reader will agree that the ingenuity and the skill of the operators are worthy of the highest praise. The results are both wonderful and suggestive, and it is difficult to say which is the more remarkable—the improvement in the cosmetic appearance or the benefit in many cases to the functional utility.

The papers all deal with the repair of the injuries of the jaws and of the nose, and are so clear in their message that nothing but the importance of that message justifies our emphasising it. In the carrying out of the procedures for the repair of the jaws and of the overlying soft parts the fundamental principle must be grasped that the surgeon and the dental surgeon should participate in the work, if the best results are to be obtained. The surgeon will make the flaps, he will implant pieces of bone and cartilage, but unless he has the skilled assistance of the dental surgeon he cannot obtain perfect replacement of the fragments which only the work of the dental surgeon can give; the coöperation of the two is essential, while at any stage the help of the artist is of enormous value both for the devising of procedure and for the visualising of an ideal. In each direction Professor TONKS'S aid to the surgeons has been striking. When the injury to the lower jaw has been great, it is necessary that some rigid support shall be added to replace the lost bone When the loss is less it may be possible, by careful attention to the position of the fragments, to obtain bony union, but natural consolidation may be the work of months, and the expectant treatment thus become worse than more thorough dealing with the condition. But fragments of bone almost separated from the soft tissues may survive and assist in the union of the bone, and it is therefore of great importance not to remove unnecessarily any pieces which give the least hope of survival. Yet to obtain a useful jaw the fragments must be placed and held in a position suitable for their consolidation. Good results can here be got by the employment of dentures and other forms of splints so designed as to keep the fragments in position. When, however, it is clearly hopeless to expect bony union of the fragments, on account of the large loss of bone, other methods have to be employed. A rib offers great advantages for replacing a portion of the mandible. An osteo-cartilaginous graft can be used and can be so placed that the point of its greatest convexity is in the site of the chin, but in all these elaborate cases it is essential that the soft parts shall be fully formed before the bone or cartilaginous transplant is placed in position. To provide the new soft tissues is not always easy. The cheek can supply only a limited amount of new tissue; if more is taken the resulting deformity will be as conspicuous, nearly, as that which it was proposed to set right. Flaps have to be taken from other parts, and here the ingenuity of the surgeon is greatly called upon. Major H. D. GILLIES has employed single- and double-pedicled bridge flaps cut in many new methods. A single-pedicled bridge flap is, of course, made by the transference of a broad flap of skin from a neighbouring part over untouched skin, and after ten days or a fortnight, when the flap has taken a firm hold in its new position, the pedicle is divided from the transplant and then replaced in its former position. Major GILLIES has improved on this idea; he has employed double-pedicled bridge flaps. A broad band is taken, for instance, from the scalp; it remains attached at the two ends, it is then turned down into the new position, and there it is fixed by sutures. The flap benefits by the double blood-supply, so that the risk of sloughing is markedly reduced. When the flap has taken firm hold the pedicles are divided and replaced in their former position. In this way Major GILLIES provided one of his cases with a new lower lip and chin, and as the flap was taken from the scalp the patient had a beard also, while a bald head is left for future treatment. Captain FRY'S paper dealing especially with fractures of the upper jaw shows how it is necessary in such cases to support the skin of the face so as to hold it out in the right position. Here the art of the dental surgeon comes into play, for only by means of a prosthetic appliance can the appearance of the face be regained. By steady expansion of the splint the soft parts are moulded, with the happy results displayed last week by Captain FRY'S pictures.

The papers published this week deal especially with the repair of the nose. Lieutenant SECCOMBE HETT has contributed a valuable note on the utilisation of portions of the walls of the nose to repair nasal deficiencies. For instance, he takes a portion of an inferior turbinal bone to fill a gunshot perforation of the hard palate. In cases of the loss of the upper part of the bridge of the nose the middle turbinals

have proved useful for filling the hole and also for supporting a skin flap. The inferior turbinal has formed the base of a new ala, even when it has had to be put on the other side of the nose, a left turbinal being transferred to the right ala. In one case, where the bridge was greatly depressed with undue prominence of the tip, the tip was lowered by removal, a submucous resection was made of the septum, and the removed cartilage was utilised to obliterate the depression. Sometimes the sunken nose can be raised by a piece of septal cartilage removed from another case, and a piece of costal cartilage may be employed in the same manner. Captain AYMARD'S article deals with the same subject. He shows what conditions are necessary to produce good results, and he describes how to form the framework and how to provide the soft structures. Sometimes he forms the new nose on the patient's shoulder, and then transfers it by means of a long pedicle to the face. A paper read by Mr. PERCIVAL COLE before the Medical Society of London last week, which we shall publish shortly, gave many striking examples of the manner in which skin can be employed to replace mucous surfaces, and in this way most valuable developments in use and appearance are obtained. Only those who have seen these cases before and after the operations can appreciate fully the good that can be done. Infinite patience on the part of the surgeon and the patient is needed to obtain the desired results, but these may be very good, and we all must rejoice that so much can be done for our men mutilated in the war.

The Nursing Profession and Voluntary Registration.

JUST as sick-nursing, as we now understand it, took its origin in one of the most disastrous war campaigns of the nineteenth century, so the martial conditions of the last three years are likely to bring about a change of a permanent nature in the profession of nursing. It is true that there has been continuous effort on the part of public-spirited people for nearly 50 years to fix a recognised standard on sick-nursing by Act of Parliament, and in so doing to protect the public against inefficient and fraudulent service, whilst assuring a definite status to the nurses themselves; but the movement failed by reason of the lack of unanimity among nurses and others interested in nursing as to the need for State registration and the advantages to be derived from it. Nor was this to be wondered at since the work of a nurse is of so varied a character that opinion is sure to be divided as to the nature and details of the training to be provided. Obviously the qualification required by a hospital sister is widely different from that desirable for a district nurse or one attached to a tuberculosis dispensary. For the moment at least any standard imposed upon nurses from without by an Act of Parliament appears unattainable in view of the fact that no measure except an agreed one can hope to get through; but the support which is being given by nurses of all shades of thought and kinds of practice to the College of Nursing, which owes its origin to the indefatigable energy of Sir ARTHUR STANLEY, shows the need which is keenly felt by the nursing profession for some central unifying association.

Since the objects of the College have recently been the matter of some controversy it may be well to recapitulate them here. On the printed application for registration they are stated to be:—

1. To organise the nursing profession.
2. To secure State registration for the trained nurse.
3. To make and maintain a register of trained nurses, and by this means to protect the public.
4. To protect the interests of trained nurses.
5. To raise and maintain the standard of training.
6. To establish a uniform curriculum of training and one portal examination.
7. To establish lectureships, scholarships, and in every way to promote the advancement of the nursing profession.

The concrete advantages of this programme have nowhere been more persuasively stated than by Miss V. MATHESON, secretary of the Irish Board, at a meeting held in Belfast on July 26th, and now republished as a pamphlet.[1] Miss MATHESON describes her article as a nurse's talk to nurses, and we are content to leave her to address her own proper audience; but we cordially endorse her view that it is essential for the body of nurses as a whole to have some outward expression of their ideals, and apart from the work of each as an individual. Some nurses, she rightly observes, find this expression in their hospital training school; but hospitals bound by their constitutions are obliged to devote their funds primarily to their patients; and there is seldom any surplus available for the interests of their nursing staffs, although undoubtedly the services rendered by probationer nurses as wardmaids and scrubbers save the hospital management many thousands of pounds a year. Miss MATHESON asks for a centre of nursing education at which examinations shall be held, scholarships offered, and where interchange of information and advice is always available. Those who have worked unavailingly for a one-portal entry to the medical profession will be the first to see the advantages of this desirable unification for nurses. These things are included in the programme of the College of Nursing, which has already obtained a voluntary register of over 7000 nurses, all of whom have produced evidence of efficient training in general civil hospitals.

We believe that the time has come when all those who have the real interest of nursing at heart, as well as the imagination to see how these interests can best be furthered, may well unite in assisting such a scheme of voluntary registration as a first step towards the raising of the status of the nurse and of giving her the standing which is her due. In saying this we are in full unity with the contention that any body which claims to control the training and registration of the nursing profession should be elected by nurses themselves on a wide basis representing all kinds of nursing activities. The permanent Council of the College of Nursing is to be elected on this basis, and we see no reason to doubt that the nurses who are now

[1] The College of Nursing: A Nurse's Talk to Nurses. To be obtained from the Secretary, 6, Vere-street, London, W. 1.

registering will be able to impress their wishes upon any temporary nominated Council. In fact, if voluntary registration becomes general, the position will be unassailable. This implies the laying aside of any personal feeling which may have been present on either side. Change of feeling, brought about by the introduction of new factors into the question, will be regarded as a token of public spirit and not as a sign of weakness or illogicality.

Annotations.

"Ne quid nimis."

THE WEEKLY HOURS OF EMPLOYMENT OF MUNITION WORKERS.

THE investigations of the Health of Munitions Workers Committee, presided over by Sir George Newman, have produced already, and will continue, no doubt, to produce, results of not merely transient and immediate interest or importance. It was appointed to consider and advise on questions of "industrial fatigue, hours of labour, and other matters affecting the personal health and physical efficiency of workers in munitions factories and workshops." The conclusions arrived at by it will serve as a guide to those who regulate the hours of industrial work long after the immediate urgency of bringing the output of war material to the highest point attainable has ceased to confuse the issues involved and to prejudice the opinions of those anxious for the country's safety. In its Twentieth Memorandum (Cd 8801) the committee deals with "weekly hours of employment," its observations being thus supplementary to those recorded in Memorandum 5, in which "hours of work" were considered, as well as to those in its First Memorandum, issued when the urgent demands of the Army had led to ceaseless toil throughout the week and made the expediency of Sunday labour a pressing question for employers and employed. The committee now can review its past conclusions in the light of experience collected during two long years; it is able to take into consideration with the actual facts before it the effect of labour prolonged not through months but through years, and to judge with regard to women's work from its effect upon a hugely increased number of subjects engaged upon a greater variety of processes than formerly. The general tendency of previous memoranda has been to show that a point will always be reached in the work of men, women, and the young alike, at which longer hours spent in the factory fail to increase output, and at which, if the hours of labour are made longer still, the productiveness of the worker will actually be diminished. Fuller, more complete, and more accurate data gathered from the actual experience of those most interested in watching the productiveness of individual factories have confirmed this opinion. The committee is now able to report, with particular reference to the week as distinguished from the day, that a reduction varying from seven hours to 20, where it has been tried, has in no case had for its result more than an insignificant diminution of total output, while on the average it has produced a substantial increase. Alterations of hours may have different effects in different operations, and experience must decide in each case the exact limit which cannot safely be exceeded, but that the hours worked weekly can, as a rule, be reduced with advantage to a total of from 50 to 55 hours is a general conclusion summarised in paragraph 6 of the Memorandum now before us. In connexion with the question of production account has to be taken not merely of the slackness of work, voluntary or involuntary, which is the natural result of long and continuous toil, but of the loss of time caused by absence through sickness, and by bad time-keeping. Nor should it be forgotten that the sickness of the worker not only affects his or her immediate personal comfort, but may diminish earning capacity during future years. Long hours, moreover, are responsible not only for actual physical breakdown, but for nervous irritability tending to increase industrial unrest, as well as for such undesirable social conditions as are likely to affect those whose homes become merely sleeping-places for overweary persons. The committee therefore reviews its opinions formerly expressed, having convinced itself that the maximum limits of weekly employment already suggested by it are too high except for quite short periods, and advises that, regard being had to all the circumstances of particular cases, more reduction may safely be made. It is further of opinion that the time is favourable for such reduction to be brought into effect, with benefit to the workers' health and without injury to that sustained output upon which our existence as a nation may be said to depend.

SERUM DISEASE IN CEREBRO-SPINAL MENINGITIS AND DIPHTHERIA.

WE published in a recent issue of THE LANCET (Dec. 1st) three interesting communications on the subject of serum disease and the rashes associated with it. Two of the papers, those by Surgeon-General H. D. Rolleston, R.N., and Dr. Claude Ker, were contributions to the discussion before the Royal Society of Medicine on the Manifestations of Serum Disease which may Follow Intrathecal Injections. There is a striking concord between the results arrived at by these two observers, and as their papers contain some valuable practical suggestions they deserve to be widely read. Surgeon-General Rolleston records that in 96 bacteriologically proved cases of cerebro-spinal fever occurring during the third year of the war and treated by serums a serum reaction occurred in 58, or 60 per cent., of those who survived for ten days or more. In nine of these cases, or 15·5 per cent., the serum rash was preceded or accompanied by a definite recrudescence of meningitic symptoms. It is now well recognised that injection of serum into a healthy intrathecal space produces an aseptic meningitis, and it is established that such a serotoxic meningeal reaction after intrathecal injections in cases of cerebro-spinal fever, as in the 9 cases here mentioned, may give the symptoms of a recrudescence of the disease, and that under these circumstances a fresh injection of serum may aggravate these manifestations and do harm rather than good. Surgeon-General Rolleston suggests that a decision as to whether more serum should be given or not can be made by examining the cerebro-spinal fluid for meningococci, which would indicate the existence of an actual exacerbation, or by examining for glucose, which would be present in the serotoxic reaction, absent in a relapse of the meningitis. He further points out that this meningeal manifestation of serum disease only

develops after intrathecal injection, and he emphasises the importance of a general recognition of its occurrence. Dr. Ker arrives at almost identical conclusions. He observed serum sickness in 36 out of 48 cases of cerebro-spinal fever who lived 9 days or more—i.e., in 76 per cent. He only observed an aggravation of the meningeal symptoms during the serum sickness in two cases, though he found increased turbidity of the cerebro-spinal fluid and other indications of meningeal reaction in several others. In all of these cases the fluids withdrawn reduced Fehling's solution, and he emphasises the convenience of this test. Both Surgeon-General Rolleston and Dr. Ker point out that in spite of the frequency of rashes after intrathecal injection of serum, it is not established that they are more frequent than after subcutaneous injection. Dr. Ker discusses the effect of sharp attacks of serum sickness upon the course of the disease, and states that he regards them as advantageous rather than otherwise. He is convinced that in diphtheria a smart serum reaction, especially when accompanied by pyrexia, is often of great benefit to a patient with feeble pulse and subnormal temperature, and he thinks that many patients with cerebro-spinal fever are improved by these reactions. The third communication is a letter from Dr. Frederic Thomson giving some interesting details of the rashes occurring after the administration of anti-diphtheritic serum, showing that they are still very frequently observed and that a circinate erythema is not uncommon, being next in frequency to the urticarial type of rash. These interesting observations on serum disease and its significance should stimulate further investigation.

THE INTRAMUSCULAR INJECTION OF CALOMEL IN THE ENTERIC FEVERS.

IN the *Annali de Medicina Navale* for July Captain Galatà, of the Medical Department, Italian Navy, recommended the treatment of enteric fevers by intramuscular injection of calomel. The treatment which he laid down is commenced in the first week of the disease, and 1·5 gr. of calomel is injected into the muscles of the buttock on the first and seventh day, 0·75 gr. on the fourth and tenth; the calomel is slowly absorbed at first but later more markedly; after the third injection temperature falls, the nervous symptoms decrease, and by the fourth injection the patient is almost well. He used this treatment with great advantage in seven out of nine cases of different infections which recently came under his notice.

EYE-STRAIN AND THE CINEMA.

OF recent years the cinematograph has come to play a very important part in the entertainment of the British public, and the report of the Cinema Commission recognises it as a valuable means of education, but with certain drawbacks. The question of eye-strain has claimed a good deal of attention, and the Commission, besides recommending the continuous illumination of the hall by means of screened lights and short intervals of bright lighting between successive films, advises the formation of a special committee with representatives of the Illuminating Engineering Society to go carefully into the whole question. The luminous mist produced by tobacco smoking is a factor which greatly complicates the solution of the problem. Turning from the projecting beam to the films themselves, two defects especially have marred the comfort of the observer. There is and probably always must be, the ordinary flicker due to the mechanical impossibility of avoiding flaws in the films, and in addition there has been until now what may be called a wobbling movement of the picture as a whole. The latter takes place either in the horizontal or vertical plane and is a source of great annoyance to the observer and probably more detrimental to the eyesight than the flicker. Rapid movement of the eyes in following the image as it shifts across the screen soon becomes painful, and the quicker the movement the greater the discomfort. When the wobble is rapid the picture becomes very like what surrounding objects must appear to a person with nystagmus. Fortunately, a method has been discovered of annulling these oscillatory movements. We have had an opportunity of seeing the "cinematograph projection steadier," invented by Mr. John Dunlop, of Glasgow, by which remarkably steady pictures are produced. The invention is very simple, the film passing between rollers before it meets the projecting beam of light. Mr. Dunlop has certainly succeeded in overcoming in large degree the second of the defects we have alluded to and in relieving cinema eye-strain. Other reforms we hope will follow.

NEPHRITIS IN THE BELGIAN ARMY.

HITHERTO there has been a lack of information as to the occurrence of acute nephritis among the Belgian troops. This has now been given by Dr. Moret,[1] who has found it in about 1 per cent. of the army in the field. He states that this is not such a high proportion as that existing in the French and British troops, and that the latter have suffered most severely of all. He mentions the interesting point that latent albuminuria has been found in apparently healthy soldiers more frequently in the Belgian Army than in other armies. In the French Army Ameuille found latent albuminuria in 1·87 per cent. of the combatants and in 1 per cent. of the non-combatants. Macleod found it in 4·73 per cent. of combatants in the British Army and in 2·95 per cent. of non-combatants.[2] The Belgian Army shows 5·77 per cent. of latent albuminuria. He therefore expected that the incidence of acute nephritis in the Belgian Army would be higher than that of her Allies, and was relieved to find this was not the case. We should have supposed from this that he would have come to the conclusion that latent albuminuria had no real connexion with acute nephritis but was of the same order as the orthostatic or "functional" albuminuria often found in young adolescents. Curiously enough, his argument is in the opposite direction. He concludes that the conditions of life at the front, especially of life in the trenches, produce a hypersensitiveness of the kidney predisposing to nephritis. He regards fatigue as the principal factor which produces toxins that injure the renal filter and excite the latent albuminuria. Various infections, often of quite a mild character, aided by cold, act on the kidney as the point of least resistance and produce an explosion of acute nephritis, to which the name of war or trench nephritis may be given. He maintains that it is not a new entity, but the classical acute nephritis, which has become m...

[1] Arch. Médicales Belges, November, 1917.
[2] THE LANCET, 1916, ii., 463.

frequent among soldiers, and that trench life predisposes to other forms of nephritis besides the acute type. He urges the importance of examining the urine of all soldiers who complain of fatigue, difficulty in walking, and of lumbar pain after marching, and of giving all troops proper periods of real rest. Dr. Moret makes a point against the theory of a specific infection when he shows that a number of infective organisms, often of low virulence, have been held responsible by various observers. He regards these as merely producing their effect on a kidney with its resistance already lowered and the subject of latent albuminuria. But in that case not only should we expect more correspondence between the incidence of latent albuminuria and of acute nephritis in the different armies, but we should anticipate that as the strain of war continued nephritis would become more frequent. Fortunately this does not appear to be the case. It must be admitted that so far no satisfactory explanation has been given of the frequency of acute nephritis in this war as compared with all others except the American Civil War. The third annual report of the Medical Research Committee, which has just been issued, is not able to carry our knowledge of the etiology of war nephritis any further yet, although it is gratifying to know that researches are still actively in progress.

INFANT MORTALITY IN INDIA.

THE question of infant mortality occupies a prominent place in the annual report of the Sanitary Commissioner of the United Provinces recently published. The actual number of infant deaths during the year was 423.130, which is equivalent to 209 per mille of the births. The greatest mortality in the United Provinces was attributed to tetanus, occurring as the result of uncleanly midwifery. In most of the districts over 50 per cent. of the infantile mortality was set down to this cause. It is evident, however, that the figures cannot be relied on, and the health officers of the leading municipalities have been instructed to inquire into the age of each child reported to have died of tetanus, and also to make a personal diagnosis. By this means it is expected that the real significance of tetanus as a cause of infant mortality will have been ascertained by the close of the current year. It is impossible to contemplate the great problem of infant mortality in India in its widest aspects without appreciating the tragedy which it presents, or realising how much educated Indians might do to reduce the evil by pointing out to their less-favoured fellow countrymen the results that must inevitably follow violation of the laws of health.

MALARIA PROBLEMS.

A QUESTION which has lately caused some anxiety is whether malaria will again become endemic. If we really understood why it had disappeared from this country we might be in a position to answer the question, but the explanations so far given of the disappearance of malaria are partial and therefore unsatisfactory. A recent number of the *Paris Médical* (No. 44, Nov. 3rd, 1917) deals with this and other aspects of malaria. It is hopeful to be informed that in three years only 100 autochthonous cases have been noted in France and none in the Marseilles district, where there is much imported malaria, and, of course, anophelines. It seems as if there were still some influence unknown, the "regional factor" of Stephens and Christophers. Much has been written by our French colleagues as to the differential symptoms of primary and secondary malaria, but we do not believe it possible to tell whether a patient's attack is the first or the fiftieth. These terms have often been employed loosely, the definition here given being: primary malaria is infection with malignant tertian parasites, secondary malaria with simple tertian. But does malignant tertian change to simple tertian? There are no facts that we know of which show that a malignant tertian infection of West Africa becomes a simple tertian later. It certainly does not in West Africa itself, because there simple tertian is rare, malignant tertian universal, nor have we seen a malignant tertian from West Africa change to a simple tertian in this country. That the Macedonian cases did so change in November, 1916, is well known to microscopists, but the explanation may be that the patients were doubly infected at the start. This question of the unity of the species of malaria parasites could probably be settled by the observations of West African cases in this country. Will the war statistics on malaria give the *coup de grâce* to the special parasite theory of blackwater fever? We should have expected, with a writer in the *Paris Médical*, this hypothetical parasite to have become epidemic in its manifestations in Macedonia, but we believe it has not done so. Cases of blackwater fever have been observed so far only among malarias, not in dysenteries, paratyphoids, cholera, or any other condition. Concerning the mode of administration of quinine much has been learned during the last few years, but Mr. Stephen Fox's letter in our correspondence columns shows that finality has not yet been reached. Prophylactic treatment is not discussed in the French journal. So far as we know there is no experience in this war to draw upon. What an opportunity for a great experiment, and one if it had been successful that would have resulted in the saving of life, money, and time, and, if unsuccessful, at least of quinine! It is only by the method of controls not taking quinine that the value or want of value of any prophylactic dose can be determined. We believe the evidence points to the conclusion that the 5-grain or even 10-grain dose daily is useless as a prophylactic. Paroxysmal treatment, under normal conditions, presents no great difficulties and is usually successful, but we learn that in Macedonia failure has not been uncommon. We would note in passing that the dilution of the dose used for subcutaneous injection—viz., 2·8 grammes of quinine-urethane in 30 c.c. of saline—is unnecessarily bulky, and so for the intravenous injection 2·8 grammes in 500 c.c. Experience has shown that simple tertian parasites are difficult to eradicate from the body. The ordinary paroxysmal treatment—oral, intramuscular, or intravenous—which as such is usually so successful, does not in the doses ordinarily used effect a real cure—i.e., an eradication of parasites from the body. Hence the necessity for post-paroxysmal treatment with that object in view. What is the best method of obtaining this end? This, as recognised in these papers, can only be ascertained by observations on a considerable number of cases. The following methods are discussed:—1. A common procedure, viz., grains 10 to grains 20 daily, for considerable periods, is not a good method, for as many as 30 per cent. may relapse at any particular time while following this mode of treatment.

2. Grains 30 on three consecutive days each week is much better, for it keeps the relapses down to 5 per cent. 3. Treatment of relapses only—grains 30 during the attack and for two days more if necessary until the temperature falls—is a method which also keeps the relapses down to about 5 per cent. It has the merit, like the second mode of treatment, that it is an interrupted one, and the additional merit that quinine is not given unless it is actually necessary. The drawback to all these methods is that they probably are no more curative (in a month) than the original paroxysmal treatment. With the lapse of time, no doubt many of them will be curative, but a post-paroxysmal treatment is required which, while it is as such efficacious, will at the same time give a good chance of cure within a month or less. From this point of view we believe that these treatments will be found unsatisfactory. Neo-salvarsan treatment is recorded, but the cases are too few to enable us to estimate its value as a curative drug. Finality has not yet been reached in our knowledge of how to administer quinine in order to obtain a permanent cure, if such can be obtained by its use, and if it is not Nature that effects it.

THE CARE OF THE BLIND.

THE Departmental Committee of the Local Government Board on the Welfare of the Blind has recently issued its report (Cd. 8655). Mr. W. Hayes Fisher, President of the Board, has now appointed a committee of ladies and gentlemen to advise the Department on matters relating to the care and supervision of the blind. Most of the members have had great experience in dealing with the education and after-care of blind people, and the selection appears to have been made with discretion. There is, however, one serious omission: there is no medical man or ophthalmic surgeon upon the committee. The Departmental Committee had an ophthalmic surgeon among its number, as well as two other medical men. They invited the Royal Society of Medicine to give them help in their deliberations, and a subcommittee of the Ophthalmological Section devoted much time and trouble to the subject. Mr. Hayes Fisher, writing to the *Times* of Dec. 11th, excuses himself for the absence of any medical representative on the Advisory Committee by saying that "nine-tenths of the committee's time will be taken up with the consideration of administrative problems," and that "under existing circumstances it would not be right to make a further demand upon the time of any of our eminent ophthalmic specialists, who are already so fully occupied." In the ordinary affairs of civil life it would not be thought courteous to obtain the gratuitous advice of experts and then proceed to put their recommendations into action without inviting their coöperation. "Under existing circumstances" there may still be some of the older ophthalmic surgeons whose offers to the War Office have not been accepted and who are sufficiently free to undertake other duties. At any rate, they are themselves the best judges of the time which they have at their disposal, and it is regrettable that the Advisory Committee will be deprived of their assistance.

MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of the Medical Insurance Agency was held at 429, Strand, W.C., on Nov. 22nd, when the chairman, Dr. G. E. Haslip, made a statement with reference to the work of the agency from May to November, which showed that the amount of business transacted continued satisfactory, in spite of difficulties owing to unsettled conditions as a result of the war. On the whole, it appeared from his statement, the bulk of business has been maintained in every section. Motor business continues to grow, in spite of the shortage of petrol and the number of men away on military service. The agency also hold many cars covered against the fire risk only during the absence of the owners, and on their return it is not unreasonable to anticipate considerable extension of business. In the meantime the amount of premium received for the fire risk is less than for full risks, which naturally influences the amount received for commission. A satisfactory feature continues to be the amount of life business placed, without restriction to any particular office, but in accordance with the special circumstances of each case. A distribution of surplus profits being again possible this year, the Committee resolved that a further sum of £500 should be voted for medical benevolent purposes, making a total distribution of £1,000 during 1917, as compared with £705 in the previous year. The £500 were allocated as follows: Royal Medical Benevolent Fund, £100; Royal Medical Benevolent Fund Guild, £100; Epsom College Benevolent Fund, £50; Royal Medical Benevolent Fund Society of Ireland, £40; War Emergency Fund (Royal Medical Benevolent Fund), £210. As a result of this distribution the total sums allocated to medical charities have reached £3405. The votes at the disposal of the Committee for St. Anne's School, in return for grants made, have been given to the daughter of a medical practitioner.

THE library and offices of the Royal Society of Medicine will be closed on Christmas Eve, Christmas Day, and Boxing Day—i.e., Dec. 24th, 25th, and 26th.

Major Sir Filippo de Filippi, K.C.I.E., will deliver a lecture, illustrated by lantern slides, on "The Sanitary Services of the Italian Army," at University College, London (Gower-street, W.C.), on Tuesday next, Dec. 18th, at 5.15 P.M. The chair will be taken by the Vice-Chancellor of the University. The lecture is open to all without fee or ticket.

THE LANCET, VOL. II., 1917: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 29th will be ready early in the New Year. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

SANITARY CONFERENCE AT KARACHI.—A sanitary conference was held in Karachi recently. The conference took the form of a series of popular demonstrations on sanitary matters by means of lectures, illustrated by many lantern slides and cinematograph films. The lecturers were recognised authorities on the subjects with which they dealt, which included malaria, tuberculosis, cholera, rats and fleas in relation to plague, and methods of rat destruction, yellow fever, public health, functions of a municipality, &c. The conference was held under the auspices of the municipality of Karachi.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Committee was held at the offices of HE LANCET on Monday, Dec. 10th, Sir RICKMAN GODLEE the chair.

A letter was read from the medical officer of health of ilford Haven, referring to the need or otherwise of the elgian workers at that port being attended by a medical an of their own nationality. The medical officer explained at the Belgian community was smaller than it had been. id was being attended by the local medical practitioners that the help of a Belgian practitioner was no longer quired.

Dr. DES VŒUX submitted a financial statement which owed the present position of the Fund to be as follows:—

Belgian Doctors' and Pharmacists' Relief Fund.

TREASURER'S CASH ACCOUNT. 1ST JULY TO 30TH NOV., 1917.

17.								
July.	To Balance...	£5477	13	4	By Relief	£4012	0	0
	,, Interest...	34	0	7	,, Clothes	10	10	0
					,, Administration expenses		2	6
					,, Balance Cash at Bank...	1489	1	5
		£5511	13	11		£5511	13	11

We have examined the above account with the books and vouchers the Fund, and certify it to be correct according to the books. In our nion the receipts and payments have been fully recorded, and we re compared the receipts with the published acknowledgments and re had produced to us certificates as to the correctness of the balance shown. CREWDSON, YOUATT, AND HOWARD, Chartered Accountants, Auditors.

0a, Basinghall-street, London, E.C. 2, 5th Dec., 1917.

This pecuniary position corresponded with the estimate of Committee, earlier in the year, that the funds in hand uld enable a mensuality of £800 to be sent during 1917 to lgium, but that the end of the year would see the practical haustion of the Fund. It was decided that £700 should sent for the month of December, and that the amount ilable for January should later be fixed. Dr. Des Vœux announced that temporarily the clothes department had en shut up, the premises having been taken over by vernment, but that he had found a lady willing to ervise its continuance when the necessary accommodation was available. For the moment the clothes have en stored.

The Committee debated the future prospects of the Fund, ring regard to the fact that the sum remaining at their posal would be exhausted by the mensualities of December l January, and came to the unanimous conclusion t an attempt should be made, despite all the attend- difficulties, to raise more money. A letter from Mr. B. Poland, Director for Europe of the Commission Relief in Belgium, who until the outbreak of hostilities ween Germany and America had been resident in gium, was read, which described in moving terms e the terrible plight of the Belgian middle-class ulation and the unbounded gratitude of the medical pharmaceutical professions for the assistance which been afforded them by their British colleagues. the face of such a letter the Committee found it a amount duty upon them to proceed with the difficult of raising further money, and it was decided that steps uld be immediately taken to this end. It was arranged a letter signed by the Committee and placing the ation before the medical and pharmaceutical professions uld be published in early issues of the medical and rmaceutical press, and that Mr. Poland's communication, ded to above, should also be published in the same nals and circulated widely in other quarters.

ELFAST MEDICAL STUDENTS' ASSOCIATION.—On ay, Dec. 7th, at Queen's University, Belfast, Dr. S. kington, President of the Medical Students' Asso- ion, having delivered his opening address dealing with progress of medicine, Professor J. Lindsay gave a ire on the prospects before the medical student, which lescribed as bright for all. In replying to a vote of ks, Dr. Lindsay said the scheme recently adumbrated ee medical treatment for everyone would be a difficult It would come up against specialism and medical arch, and would tend to a dead level of mediocrity.

MEDICAL RESEARCH COMMITTEE.

THE THIRD ANNUAL REPORT.[1]

WE dealt last week with some of the more general aspects of the work of the Medical Research Committee, and now pass on to consider in detail certain departments of it.

The Central Institute and its Departments.

The Mount Vernon building used until August last for the study and treatment of military cases of heart disorder is now to be employed for the care of the special disabilities incident on flying, the heart cases having been transferred to larger accommodation at Colchester.

Department of Bacteriology.—The department has continued to turn out work of the first interest. The diminished alkalinity of the blood shown to be present in cases of gas gangrene has led to successful treatment of these cases by the infusion of alkaline solutions. Further work on the emigration of white blood cells and their place in the general physiology of wound healing has been done. The classification of cases of war nephritis has been advanced a stage, and investigations made into the best methods of skin-grafting, into the various types of *B. dysenteriæ* Flexner, and into the bactericidal and tissue-destroying effects of certain groups of antiseptic substances. The special beds at St. Mary's Hospital set apart for research in connexion with the Department have had to be abandoned owing to shortness of staff.

Department of Biochemistry and Pharmacology.—An investigation into the action in experimental dysentery of the alkaloids of ipecacuanha has had practical results, as well as another into the effect on amœbic infection of the Mexican bitter-bush, *Castela nicholsoni*. Work on the nature of shock-like conditions and on the properties and commercial preparation of the flavine antiseptics has occupied much attention. In addition, confidential inquiries of various kinds have been carried out for Government departments. One member of the staff has inquired experimentally into the physiological actions of alcohol for the Central Control Board, and the department has benefited by the help of Dr. A. N. Richards, professor of pharmacology at Philadelphia University.

Department of Applied Physiology.—This department has been decentralised and made partly perambulatory to meet special needs, relinquishing its rooms at the London Hospital Medical College. Pressing work has been done on the composition of workers' dietaries and on economical methods of cooking foodstuffs. The principles of ventilation have been further investigated by the cata-thermometer and the emission of radiant heat from the human skin accurately measured. Synthetic biochemical processes, especially in relation to the conversion of the energy of light into chemical energy, have been further studied, as well as the physiological problems of flying at high altitudes.

Statistical Department.—In addition to the great task of preparing medical statistics of the war, the epidemiology of phthisis has been studied with the provisional conclusion that two allied organisms are concerned, one affecting early adult and the other middle life, each with a distinct geographical distribution. Infant mortality, the periodicity of measles epidemics, and the span of human life, as illustrated in the contributions to the "Dictionary of National Biography," have also been subjects of inquiry.

Department of Clinical Research.—This will now be concerned both with the military cases of heart disorder at Colchester as well as with the disabilities due to flying at Mount Vernon.

Army Medical Statistics.

Work in this field has grown to enormous proportions, demanding a clerical staff of 103 persons. Since Jan. 1st, 1917, the War Office has provided the salaries of typists and sorting clerks while the Research Committee has supplied the staff itself and other resources. The records will form the statistical basis of the medical history of the war and, in addition, a source of essential facts for the prompt settlement of all claims for pensions and allowances. This fact in itself entitles to a grant of public money. The records have already been used in tracing the after-history of large groups of cases of gas-poisoning, nephritis, gunshot wounds of the chest, and aneurysm. A military officer of high standing has been appointed to represent the Committee in France, with the result that a general system of records has been evolved with complete success. In place of the case-sheet the Army field medical card has been altered to form a continuous diary of each casualty's clinical history while overseas, which returns with him to the United Kingdom for the information of any medical officer into whose hands he comes. This card is the same size as the Research

[1] To be obtained through H.M. Stationery Office. Price 6*d*.

Committee's index cards and can be filed with them. Note-taking forms and blank diagrams have been supplied by the million, enabling special records to be kept of special subjects such as abdominal surgery, head and chest wounds, fractures of bones, and injuries to joints. A pathological artist has been engaged to assist the verbal descriptions of important injuries. Mobile laboratories for bacteriological or chemical work have been further extended and opportunities afforded of throwing light on problems of military and medical importance—e.g., in the study of changes in the circulation after severe wounds and operations.

Decentralised Work.

The report considers in detail a number of headings under which special research work has been aided at civil and military hospitals and ambulances. Some of these are: the disinfection of drinking-water, the chemistry of bacterial growth, typhoid and paratyphoid infections, dysentery, cerebro-spinal fever, spirochætal jaundice, trench nephritis, the medical problems of flying. These summaries include a large part of the most important work of the Committee and work which gives great promise for the future, but they do not lend themselves to further abstraction, and this is the less necessary as many of the results recorded have been published in our columns during the last 12 months. The report concludes with an acknowledgment of the valued help and coöperation of the United States of America. On behalf of the National Research Council at Washington, Dr. H. D. Dakin gave to the Committee valuable service in France and the Mediterranean, and after his return to New York is still serving as a personal link between the two organisations. The Rockefeller Institute for Medical Research, in the person of its director, Dr. Simon Flexner, has also reciprocated, and Professor W. B. Cannon, of Harvard, and Professor Tilestone, of Yale, are in this country collaborating with the British staff. This growing coöperation for the advancement of medical knowledge between the English-speaking countries is a fortunate event, and one fraught with great promise.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inter-Allied Surgical Congress.

AT the third Inter-Allied Surgical Congress, which sat from Nov. 3rd to 8th at the Military Section of the Val-de-Grâce, under the presidency of M. Justin Godart, Under Secretary of State for the Service de Santé, *six questions* were raised on which numerous conclusions were based, some of them of great importance. With regard to the *first*—secondary and delayed complications of wounds of the brain—surgeons agreed that delayed infection of such wounds is much rarer than was commonly supposed; that organic disturbances following wounds of the brain, e.g., hemiplegia, monoplegia, aphasia, visual disturbances, frequently have a tendency to spontaneous improvement; and that epilepsy, if amenable to surgical intervention when a foreign body or splinters of bone are present, is not so in other cases. In cases of cerebral hernia lumbar puncture should be avoided during the acute febrile phase in order to avoid the possible dissemination of a local infection. Foreign bodies tolerated by the brain may be left. Cranioplasty is only indicated in cases where the extension of the cicatrix is the sole cause for the symptoms observed, except in the frontal region for æsthetic purposes. The *second* question dealt with the later results of treatment in the case of fracture of the shaft of the femur. It has long been generally recognised that results are only middling as regards the extent of the lesions, the insufficiency of reduction and of its maintenance, and especially as to infection of the focus. A primary sterilisation of the wound is the chief factor to realise. Stiffness of the joints of the knee, hip, and foot can be avoided by early movement. Adherence of muscles to callus is the origin of many disturbances of function necessitating freeing by surgical methods. Strongly marked deviation is amenable to ostectomy with resection of the callus if there is osteomyelitis. The *third* question referred to operation for injuries to nerves. The Congress admitted that the ultimate results are generally middling, especially in the case of total lesions, and when the operation takes place among suppurating tissues. Primary suture of a nerve in a *milieu* rendered aseptic by modern methods has given better results. Functional recuperation is slow, occupying months or even years, a fact which must be taken into consideration in working out compensation. The treatment of fracture of the joints (*fourth* question) has made great progress since primary sterilisation has been the object aimed at, and operative measures initiated within 10–12 hours. Comminution of the epiphysis is to be treated by gouging out and cleansing followed by immediate suture of the joint. Early resection is only indicated in exceptional cases where severe comminution is present. Primary amputation is limited to cases of extreme contusion with destruction of the principal artery. Immediate active movement gives better results than immobilisation. The *fifth* question deals with the treatment of chronic osteomyelitis, which should be mainly preventive and completed either by immediate closure of the wound after removal of all sequestra or by chemical sterilisation with secondary autoplasty. With regard to thoraco-abdominal wounds (*sixth* question), the Congress gave special attention to wounds of the diaphragm. Radioscopic examination is necessary to recognise hernia of the abdominal organs and determine the displacement of the heart. Operation is nearly always indicated, and a transpleural route by way of the thorax is generally to be preferred, associated with laparotomy when desirable.

Frostbite as a Factor in the Development of Tetanus.

Inspector-General Vincent, professor at the military department of the Val-de-Grâce, discusses in a note to the Academy of Medicine the favourable action exerted by cold and frost-bite upon the development of tetanus. The fact has long been recognised by French military surgeons. Larrey showed after the battles of Prague, Lützen, and Bautzen that exposure to severe cold at night was followed by an abundant crop of tetanus among the wounded men brought in. Before the war Dr. Vincent showed by experiment that tetanus might appear several months after the entrance of the germ when the infected part was placed in ice. More recently he established the fact in guinea-pigs that local, even more than general, humid cold is a condition favourable to the rapid development of tetanus. He observed the division of tetanus bacilli taking place in the infected limb two hours after being held under a continuous jet of cold water. Tetanic symptoms appear after a very brief incubation and rapidly kill the guinea-pig, sometimes with splanchnic phenomena. Similar conditions—low air temperature, maceration by water, reduction of temperature of the limb itself, œdema, trophic disturbances in the foot—are present in the trenches in winter. The sowing of the bacillus is effected by means of pre-existent erosions, or excoriations, or by ulceration due to frost-bite itself. At a temperature of 15° C. or below Dr. Vincent has shown that the leucocytes lose their property of taking up tetanus spores, while the dropsical fluid which infiltrates the cellular tissue of the foot and leg forms a perfect nutritive medium for the anaerobe to store up its toxin. Subsequent absorption of the fluid is then the equivalent of an injection of tetano-toxin. For this reason symptoms appear early in acute cases and may outlast the period of passive immunity brought about by injections of serum. Duration of immunity from a single injection does not, in fact, exceed 10–12 days—it is occasionally less—and can only be preserved by repeated injection. The protection afforded by antitetanus serum-therapy has reduced the incidence of tetanus as an infectious complication of wounds in general, but it still occurs under the conditions named in fulminant form in spite of prophylactic injection, as M. Bacri and M. Chavasse have reported. A certain number of their cases had received one, two, or three injections of serum over a period of 10 or 12 days, some receiving large doses. Seventeen patients who received three injections died, the majority of acute tetanus. The occurrence of splanchnic tetanus was noted in three cases.

The Control of Secret Remedies.

The Academy of Medicine has been occupied for several weeks past in discussing the terms of their reply to a question proposed by the Minister of the Interior on the subject of the control of the sale of secret remedies. The situation is completely abnormal in France and has long required definite control. In theory the offer for sale of remedies of unknown composition is strictly forbidden by the law of April 11th, 1803 those who sell or advertise such remedies being liable to prosecution. For many years, however, in

urts have not enforced this law, though it has never tually been repealed. The number of secret remedies now posed for sale is said to amount to 40,000 or more. The lution of the question is not easy at the present time, for , on the one hand, medical men are in general hostile to e offering of pharmaceutical specialities to the public thout medical prescription on the grounds of the grave nger to the public health and the prejudice to legitimate edical practice, on the other hand the sale of patent edicines represents a huge industry, not only in France elf but also for export, and the gain to the revenue om the taxes imposed cannot be neglected. Manu-cturers of secret remedies naturally have considerable ancial influence, and by publications in the general and edical press they add largely to the publishers' profits, king it difficult or impossible for adverse medical opinion be circulated. These difficulties find an echo in the bates of the Academy. M. Galippe maintained the itimacy of pharmaceutical specialities and the necessity avoiding damage to the large commercial interests which only protected by the secrecy of the composition of their ducts. M. Léger, spokesman of the committee appointed the Academy to study the question, concluded in favour a compromise. The sale of pharmaceutical specialities uld be authorised only after examination by a special nmittee of the Academy, the exact formula being deposited h the Academy, the School of Pharmacy, and the ncil of Hygiene. M. Bourquelot, professor at the School Pharmacy, demands, on the other hand, the reinforce-nt of the prohibition of the law of 1803. He suggests t preparations of genuine interest have nothing to fear m the publication of their formulas, still less the special nds of products of definite chemical composition, alkaloid ther, the purity of which can only be obtained by manu-ture on a large scale, and is vouched for by the name of firm. Publication of the composition could only damage rious commodities sold to the public without medical mmendation on specious advertisement. M. Bourquelot plies a powerful argument in support of his view when he nts out that, though the law is not enforced in France connexion with specialities of home manufacture, it is lied in the case of imported foreign products, no secret edy being admitted by the French Customs officials. If sale of secret remedies were now legalised it would be ossible to continue the prohibition of foreign specialities. y foreign countries which prohibit the import of secret edies, and therefore only admit French preparations ch give the formula on the label, nevertheless offer a ly market for some of them. The discussion is not yet ed, but it is quite probable that the Academy will pro-nce in favour of protecting genuine remedies, while the ibiting the sale of those whose spurious composition ires the suppression of the formula.

URBAN VITAL STATISTICS.

(Week ended Dec. 8th, 1917.)

glish and Welsh Towns.—In the 96 English and Welsh towns, with ggregate civil population estimated at nearly 17,000 000 persons, nnual rate of mortality was equal to 12·4, against 12 3 and 11·9 per in the two preceding weeks. In London, with a population ding 4,000,000 persons, the death-rate was 13·1, or 1·1 per 1000 above recorded in the previous week; among the remaining towns ates ranged from 5·2 in Enfield, 6·1 in Coventry, and 6 2 in West wich, to 18 8 in Hastings 19·8 in Rotherham, and 20·4 in ton. The principal epidemic diseases caused 280 deaths, which sponded to an annual rate of 0·9 per 1000, and included 108 from es, 60 from diphtheria, 58 from whooping-cough, 36 from infantile rœa, 11 from scarlet fever, and 7 from enteric fever. Measles d a death-rate of 2·7 in Acton, 2·9 in Leicester and in Bury, 3·2 ighton, and 6·0 in Dewsbury. The 1351 cases of scarlet fever and of diphtheria under treatment in the Metropolitan Asylums itals and the London Fever Hospital were respectively 7 above 2 below the numbers remaining at the end of the previous week. e deaths from all causes in the 96 towns, 156 resulted from ice. The causes of 33 deaths were uncertified, of which 6 were ered in Birmingham, 5 in Liverpool, and 2 each in Dudley, ngton, Manchester, and Barrow-in-Furness.

ch Towns.—In the 16 largest Scotch towns, with an aggregate ation estimated at nearly 2 500,000 persons, the annual rate of lity was 12·9 against 12·2 and 12 5 per 1000 in the two preceding . The 296 deaths in Glasgow corresponded to an annual rate of er 1000, and included 7 each from whooping-cough and infantile rœa, 5 from diphtheria, 3 from measles, and 1 from enteric fever. 2 deaths in Edinburgh were equal to a rate of 9·7 per 1000, and led 2 from infantile diarrhœa.

h Towns.—The 141 deaths in Dublin corresponded to an annual f 18 4, or 2·8 per 1000 above that recorded in the previous week, cluded 3 each from measles and whooping-cough, and 1 each iphtheria and infantile diarrhœa. The 103 deaths in Belfast were to a rate of 13·7 per 1000, and included 2 each from enteric fever, es, and whooping-cough, and 1 from infantile diarrhœa.

Correspondence.

"Audi alteram partem."

INTRAMUSCULAR INJECTIONS OF QUININE BIHYDROCHLORIDE IN SIMPLE TERTIAN MALARIA.

To the Editor of THE LANCET.

SIR,—In the *Annals of Tropical Medicine and Parasitology* (June 30th) issued by the Liverpool School of Tropical Medicine, in an article under this title Sir Ronald Ross is quoted as having written as follows:—

"I really do not know why this form of medication is continued in malaria. It appears to me that the only cases in which intramuscular injection is called for are those in which intestinal absorption may be checked by very marked intestinal affections, or where patients are not to be persuaded to take the drug by mouth at all. For severe cases, to judge by experimental evidence, the subcutaneous injections are worse than useless."

It is with great diffidence that I venture to disagree with such a master of tropical medicine as Sir Ronald Ross, but the experience of many years' treatment of malarial fever in one of the Federated Malay States (Perak) is very much in favour of the intramuscular injection of quinine. This fact in the treatment of the more obstinate forms of malarial fever is recognised by all medical officers practising in this part of the world. It is obvious that no one would exchange such a simple way of giving quinine as per os for a method which involves the boiling of the syringe, the solution, the sterilising of the patient's skin, and the discomfort inflicted unless there was good reason for it. Patients, especially Europeans, have confidence in the intramuscular method and constantly of their own accord ask for it, as they have been taking quinine by the mouth in 10 to 15 grain doses daily with no good results. The hospital returns show that the prevailing type of malarial fever in Perak is subtertian. In 1916 in the various Perak Government hospitals the microscopical examination of the blood gave the following admissions for malarial fever: Benign tertian, 1098; quartan, 202; subtertian, 4992; mixed infection, 198; type undiagnosed, 3370 (most of these cases had been taking quinine before admission, and no parasites were to be found in the peripheral blood). There were 599 deaths from the different types of malaria. The above figures do not include the many estate hospitals existing in Perak.

The hospital routine treatment of malarial fever is as follows:—

On admission to hospital, if subtertian parasites are found, gr. x. of quinine bihydrochloride in 12 mins. of water is given intramuscularly twice a day, until the pyrexia is controlled, generally in two or three days, when the injections are stopped, and 30 grains a day given by the mouth for 14 days. Often the two methods are combined, but the trouble is to get a patient to remain in hospital after his temperature has been normal for one week. If he insists on leaving he is instructed to take quinine 20 grains for two weeks and then 10 grains for at least three months, but whether he follows this advice is extremely doubtful. Relapses are, I regret to say, frequent, but this is probably due to reinfection (as parasites have again been found in the peripheral blood) as much as to inefficient treatment by quinine.

The recent excellent article, the Diagnosis and Treatment of Malaria, by Captain David Thomson, published in the *Journal of the Royal Army Medical Corps*, wherein he recommends 30 grains of the bromide of quinine for three weeks, is more or less followed by us, but I have grave doubts whether our patients will be able to stand the 30-grain doses for so long as three weeks, as well as his did in Liverpool. Malarial gastritis is a frequent complication in our fever-stricken patients. In the treatment of benign tertian 30 grains per diem by the mouth of the bihydrochloride for two weeks is the only form of treatment followed; it is found that quinine so given is sufficient to control the fever, but notwithstanding the continuous treatment afterwards by big doses, 15–20 grains, for months, our experience that relapses in this type of fever are extremely frequent, more so than in any other form. In fact, I look on benign tertian as the most obstinate of relapsing malarial fevers. The intravenous injection of quinine is reserved

for big subtertian infections with brain complications. In children and infants suffering from malarial convulsions quinine per rectum has been found satisfactory. Such is the treatment of the malarial fevers in Perak. A drug, however, is urgently needed to stop the relapses: galyl + quinine is now on trial, but too short a time has elapsed or too few cases treated for any opinion to be yet formed.

We all out here look up to the intramuscular injection of quinine as our sheet-anchor in all obstinate and chronic forms of malarial fever, and generally find we have not placed our trust in vain. With careful asepsis no bad results have generally been observed. Occasionally an abscess has developed at the site of injection, but this has been due to faulty technique and sometimes to the low vitality of the tissues. In a small hospital in Taiping with 60 beds for Europeans, Eurasians, and the better-class Asiatics, 672 intramuscular injections of quinine were given during the last 12 months; abscess formation 4, tetanus nil. The quinine is injected into the gluteal region about 1 inch below the crest of the ilium, and is always given by a European sister or by the medical officer himself. The patient's name is entered into a special book, and the operator signs his or her name and is made responsible for any bad results. Figures for the other hospitals have not been obtained. How the intramuscular injection of quinine acts I am not prepared to state; perhaps it is due to a slow, continuous absorption of the salt or to an attack in the rear, the quinine getting into the blood current of the spleen and bone marrow easier from this direction. But in whatever way the results are obtained, until some other better method or drug is suggested or discovered the intramuscular treatment of malaria by the rank and file of the profession in this State will certainly be continued.

The treatment of malarial fever by 30 grains daily for three weeks, as suggested by Captain David Thomson, is no doubt effective in a non-malarious country; but whereas in the tropics reinfection is the rule, such happy results as he obtained in Liverpool cannot, I fear, be our lot. The obvious reply to this is to get rid of your mosquitoes—but that is another story.—I am, Sir, yours faithfully,

STEPHEN C. G. FOX, M.R.C.S., L.R.C.P. Lond.,
Senior Medical Officer, Perak, F.M.S. Government

THE RETRACTION OF BLOOD CLOTS.

To the Editor of THE LANCET.

SIR,—When reading Captain W. d'Este Emery's interesting article on the Retraction of Blood Clots in your issue of Oct. 20th, I was surprised at the small percentage of serum yielded in many of his experiments, varying from 0 per cent. in large-diameter tubes to nearly 60 per cent. in 1 mm. tubes, his best—the 9 mm. tubing giving only 6·3 per cent. to 21·5 per cent. of serum. Later, however, with this same tubing and more suitable temperature conditions, he obtained 50 per cent. and 56·6 per cent. Captain Emery deduces that the narrow tubings of 1 mm. and 3 mm. give far better results than larger diameter tubes—and that conditions of temperature are also of great importance. With the latter conclusion I agree, but my own experience leads me to doubt the former.

In the course of the last two years I have prepared comparatively large quantitives of agglutinating serum for meningococcus from rabbits and have used several hundreds of these animals in making the sera in batches of about 150 c.c. at a time. The animals are bled to death through the carotid into large sterile test-tubes of 75-100 c.c. capacity and 38 mm. diameter, or more than double the diameter of Captain Emery's largest tubes. The blood is then incubated at 37° C. for one hour, the clot separated from the tube for about three-fourths of its circumference by a sterile wire, and after remaining at room temperature for 24 hours the serum is poured off. Previously to reading his paper I had not troubled to ascertain the proportion of serum to clot which I obtained, but I felt sure when reading it that I got larger quantities by my method than his deductions would suggest were possible. Major A. S. G. Bell, R.A.M.C. (late Fleet-Surgeon, R.N.), has recently assisted me in preparing this serum, and, in fact, at present is doing the major portion of this work; at the first opportunity, therefore, we weighed the clot and serum of a rabbit bled by this method and found that we had obtained about 76 per cent. serum and 24 per cent. clot. This result was sufficiently surprising, and we therefore measured a series of other bleedings with the following average results.

Twenty-two rabbits produced 672 c.c. of serum and 414 grammes of clot, or about 64·2 per cent. of serum and 35·8 per cent. clot by volume. It should be noted that these bloods were collected in the agar-lined tubes recommended by Dr. Gardner, and which tend, as Captain Emery shows, to prevent a maximum output of serum; nevertheless, the average percentage of serum from over a litre, in the aggregate, of blood is higher than the best figure Captain Emery gives. The 76 per cent. serum from the first rabbit was got from a plain tube without agar, and four rabbits were therefore bled into plain tubes, with the result that these five rabbits gave 188 c.c. serum and 104 grammes clot, or 66·7 per cent. and 33·3 per cent. respectively by volume. The total for 27 rabbits, therefore, is 64·7 per cent. serum and 35·3 per cent. clot.

Captain Emery does not say whether the percentage is by weight or volume, but I show it by volume, taking the specific gravity of clot as 1100. I noticed some time ago that the yields of serum from different rabbits varied considerably, and this I attributed to the known disproportion which exists between corpuscular and fluid contents of the same rabbit's blood at different periods—i.e., a variation in fluid percentage. We generally find a better yield of blood shortly after the morning meal, and accordingly try to bleed our animals in the forenoon. Captain Emery used human blood which does not show this variation, and this may possibly account for the disparity in our experiences. One thing, at least, is certain, that to obtain large quantities of serum by using small tubes is impracticable, for in order to procure 100 c.c. of serum, using Captain Emery's figures, some 230 yards of 1 mm. tubing, or about 50 yards of 3 mm. would be required. Some other means of obtaining maximum yields must therefore be found, and the method we are now using seems to give satisfactory quantities.

I am, Sir, yours faithfully,

Central C.S.F. Laboratory, Caxton-street, S.W. Nov. 23rd, 1917. T. G. M. HINE, Major, R.A.M.C.

THE VALUE AND LIMITATIONS OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—Of the many fallacies which beset the observer of tuberculosis statistics, not the least is the prevailing but inaccurate notion that sanatorium treatment is of itself a complete treatment of pulmonary tuberculosis and that ultimate mortality rates are an index to its value. It is true that the duration of life after treatment might afford a fair criterion of the efficacy of such part treatment, but mortality may prove nothing about the results of residence in a sanatorium except that a short stay has not achieved the impossible. After all one does not estimate the value of a "preparatory" school training by the numbers of old boys who, say, 15 years later receive an honorary LL.D.

The reason of this fallacy is clear: most of the sanatorium results on which current tuberculosis traditions were based were originally obtained from isolated institutions, either private or endowed, in connexion with which preliminary treatment was rare and after-treatment unheard of. The cases might or might not be chosen from artisan populations, but at all events they were chosen without any definite relation to the numbers of consumptives in any one district, county, or country. Now what possible light can these figures shed on the mortality rates or duration of life rates for the consumptive working population as a whole? Speaking as a past member of the staff of Midhurst, I cannot see that the Midhurst results prove anything about tuberculosis except that in variously severe cases the results vary. The patients were chosen from different sections of society and from different parts of the country, the bacillary cases were more often advanced than early, and from one-third to one-half of the non-bacillary cases were at any rate arrested on admission if not nearly so. Yet figures from these and similar institutions are often used to form the basis of deductions as to the value of the sanatorium for consumptive workers, of whose treatment it only forms a small part. Is it not time that such statements should give place to the reports of tuberculosis schemes, whose schemes, either rural or urban, give a comprehen-

idea of the incidence, treatment, and after-results for any one county or city area?

Perhaps, therefore, I may be pardoned the rôle of showman in again drawing the attention of your readers to the results obtained at the Birmingham Tuberculosis Centre. An illustration:—

A consumptive in Birmingham is no sooner notified than he is called up for examination, classified, and if found positive is sent to one of the many sanatoria and hospitals set aside for early, moderately advanced, or late cases respectively. During his absence various preventive measures are taken and all suspects or contacts dealt with. On his return he may continue treatment at the centre for as long as 18 months to two years; later he may return to a sanatorium for shorter spells of treatment if necessary, in fact, from the time of his notification he is shepherded until his recovery or death. Yet although patients may be kept on the books for three, five, seven, or ten years, there is no lack of sanatorium beds in Birmingham, no long waiting list, and the results for *all* cases, both immediate and afterwards, are far more gratifying than those of any sanatoria or semi-detached schemes, whether for private or public patients, so far noted in Britain. To take one point only—i.e., "bacillary loss"—in the Birmingham Sanatorium set apart for early cases, 57 per cent. lost their bacilli during 1916, whilst during the same year of 555 *cum leting* treatment at the centre after from six months to two years, 70 per cent. had lost their bacilli (as tested by sedimentation methods) and this in spite of a prolonged return to ordinary working and social life.

The fact is that with a certain type of bacillary case in artisan populations a relatively short stay in a sanatorium, with after-treatment at a dispensary, is all that is necessary to secure complete arrest. It is not suggested that this scheme is perfect; there is ample scope for modification and improvement, but the point I should like to insist on is that before dogmatising on the duration and results of treatment, before comparing the results in wealthy and artisan communities, and, above all, before considering whether sanatorium treatment "has utterly failed," or "partly failed," or succeeded, it would be well to ascertain whether, in fact, every county or large town has got a passable scheme, and, if not, to insist on the establishing of one. Five years afterwards the discussion on results might be reopened with profit.

I am, Sir, yours faithfully,

EDWARD G. GLOVER, M.D. Glasg.

Birmingham Municipal Sanatorium, Cheltenham, Nov. 23rd, 1917.

SIR RICHARD CROFT AND THE CASE OF THE PRINCESS CHARLOTTE.

To the Editor of THE LANCET.

SIR,—May I trespass a little further upon your space by stating how it was that Sir Richard Croft left Oxford without a degree? The explanation is given in the *Gentleman's Magazine*, vol. lxxxviii. Practising in the University city at that time was a well-known physician, Sir Charles Nourse. This gentleman had given notice of retiring. To succeed him Croft went to Oxford as Nourse's assistant. Soon after Croft's arrival, however, Nourse changed his mind and Croft returned to London.

I am, Sir, yours faithfully,

Holland Park-avenue, W., Dec. 9th, 1917. S. D. CLIPPINGDALE.

SUCCESS AND FAILURE IN THE TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—May I beg a few more lines of your space to answer, as shortly as I can, two questions which Dr. W. M. Crofton puts to me in his courteous reply to my letter in your last week's issue. Dr. Crofton asks, first, whether I think it possible by isolation to cut off entirely the sources of tuberculous infection. I do not. Leaving on one side the bovine sources of infection, I could only hope to diminish by partial isolation the number of sources of infection and thus help on the disappearance of tuberculosis, just as, we learn on the authority of Robert Koch[1] and Sir Arthur Newsholme,[2] was done in the case of leprosy in Norway. If tuberculosis continues to decline, as surely it must when happier times return, we may look forward to the isolation of a continually increasing proportion of dangerous cases, and consequently an effect which will grow year by year until it succeeds in stamping out the disease.

Dr. Crofton next asks whether I do not think his "proposal to supplement this measure by an attempt to produce by immunisation a normal resistance in everyone to the tubercle bacillus worthy of consideration and trial." Candidly, I do not. I have already given my reasons at length, and can only add that tuberculosis is not one of those diseases which confer any marked immunity, like so many others (hence its chronic course and bad prognosis when well established). We have received little encouragement from immunisation experiments in animals; and it is necessary that public effort should be concentrated on the one main thing and not be side-tracked by others of doubtful utility.

I am, Sir, yours faithfully.

Cambridge, Dec. 10th, 1917. LOUIS COBBETT.

COLLOSOL COCAINE.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 1st appears an article under the above heading by Dr. G. Barger, Dr. H. H. Dale, and Miss F. M. Durham (from the Department of Biochemistry and Pharmacology, Medical Research Committee), referring to statements published in THE LANCET and the *British Medical Journal*, embodying reports on this preparation by Professor R. Tanner Hewlett, Professor W. J. Simpson, and Dr. John Eyre, who found marked absence of toxicity and duration of anæsthesia in the samples submitted to them by us.

Scientific controversy on the difference of findings between these authorities must be deferred, as space will hardly be available for it together with the serious matters affecting personal honour and confidence which arise from that article, containing as it does, statements of fact and insinuation and indication of procedure which concern not only the persons above-named but also everyone connected with the "makers." Important omissions of material circumstances render it still further misleading. Had the authors of the article—as might be gathered from absence of mention to the contrary—purchased or otherwise acquired in the market, standard samples of collosol cocaine, for examination, their procedure and conclusions (if accurate) might merit justification, but as they omit to disclose the fact that they used various samples obtained from us, under circumstances which I mention later, a false impression is induced. Such impression is cumulatively aggravated to serious import by five separate remarkable comments in the article.

Firstly, there is mention of "a trap in which experienced observers seem to have been caught." True, this is followed by the remark, "We wish to make it clear, however, that we have no reason whatever to doubt the bona fides of the manufacturers"; and Sir William Crookes and the other scientists connected with the Crookes Laboratories will doubtless appreciate this testimony to the integrity of "the manufacturers," even at the possible expense of their intelligence.

The hypothetical criticism appearing in the article as the inspiration of the authors concerning "the other collosol alkaloids" should be tested in the light of the fact that I informed Dr. Dale at the outset that only an infinitesimal portion of the quinine used was found to be recoverable from collosol quinine by laboratory tests, and had he not specifically declined to examine anything other than the cocaine preparation, I would have emphasised the information, already given to members of the medical profession, that collosol quinine has no effect upon the parasite of malaria. The effect produced by publication of the comment without reference to our disclaimer, is obvious.

In the next place, the three authors of the article are responsible for the extraordinary and wholly inaccurate statement that the manufacturers "have withdrawn collosol cocaine from their list on hearing from us of our conclusions." No such withdrawal has been made, nor do the clinical results warrant it, but in fact we had no opportunity of even seeing—let alone considering—those "conclusions," till they appeared in THE LANCET article in which this statement as to withdrawal is made, whilst no data have even yet been furnished us to lead to such a course, nor to refute the detailed tests and reports of Professor Hewlett, Professor Simpson, and Dr. Eyre. Further, this definite statement of withdrawal appears simultaneously with a letter from the secretary of the Medical Research Committee in the *British Medical Journal*, which indicates that he, at any rate, had reason to doubt its accuracy, from perusal of my letter to that journal of the previous week, and he more accurately states that Dr. Dale

"advised them in their own interest to withdraw this preparation from their list." Then follows the remark, "This communication was of a verbal and confidential nature," but no reason is assigned for breach of the confidence.

Again, since the authors admit testing *five* different samples, exhibiting different behaviour, it is apparent that no standardised preparation was being dealt with. Dr. Dale particularly requested me to provide him with samples from different batches (and these included one which gave no anæsthesia at all), in a letter in which he said, "Any information which you are able to give as to the method of preparation would be helpful and interesting, and information so furnished by you would be regarded as confidential." Little did we suspect that under such circumstances, without affording us any opportunity of seeing the reports and conclusions, Dr. Dale would adopt the remarkable course of submitting them without our cognisance to Dr. Eyre, whom we had professionally instructed to make the preliminary tests and reports, and with the result that Dr. Eyre writes me that from the evidence Dr. Dale has put before him he is satisfied that he has been misled.

Undoubtedly such would be the case when he read conclusion No. 3, which states: "The quantity of cocaine chemically recoverable from each of the same three samples was approximately 0·24 per cent. instead of 1 per cent. *as indicated.*" The all-important fact that I not only indicated, but expressly informed Dr. Dale when giving him the samples, that only a portion of the cocaine was recoverable, and that the percentages named represented the amount of cocaine used in preparation, is withheld, with the effect that other members of the medical profession have interpreted that "conclusion," as did Dr. Eyre, with equally disastrous results. Its reasonable interpretation is that credit is due to the authors of the article for discovering that only 0·24 per cent. of the cocaine is recoverable in a preparation "indicated" as containing 1 per cent. of recoverable cocaine, either through ignorance or design, and the fact of my previous information to the contrary and the consequent discussion is suppressed. Very serious results have already ensued, and I have through your columns to seek an explanation from the authors of the article you published.

I am, Sir, yours faithfully,

LEWIS STROUD, M.A. Oxon.

The Crookes Laboratories, Dec. 10th, 1917.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

F. G. Hunt to be temporary Surgeon.

ARMY MEDICAL SERVICE.

Lieut.-Col. A. W. N. Bowen, D.S.O., relinquishes the rank of temporary Colonel on re-posting.

Lieut.-Col. S. A. Archer to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. A. R. Aldridge, C.S.I., C.M.G., relinquishes the acting rank of Colonel on re-posting.

Temp. Col. P. W. G. Sargent, D.S.O. (Lieutenant, R.A.M.C., T.F.), relinquishes the rank of temporary Colonel and to be temporary Lieutenant-Colonel on re-posting.

Major P. J. Marett relinquishes the rank of temporary Lieutenant-Colonel on re-posting, and to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

Major Walter A. S. J. Graham is seconded for employment under the Ministry of National Service.

Temp. Major (acting Lieut.-Col.) R. Wilson, C.A.M.C., relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Temp. Major E. D. Macnamara (Captain, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

Temp. Capt. F. V. Woodbury, C.A.M.C., to be acting Major.

Temp. Capt. (acting Major) A. MacKay, C.A.M.C., relinquishes the acting rank of Major.

Temp. Hon. Capt. A. M. Westwater to be temporary honorary Major.

To be temporary Captains: Temp. Lieut. H. T. H. Butt, A. Ross, C.A.M.C., C. G. Monro, W. T. Smith, A. C. Falkiner, J. N. Glaister.

To be honorary Captains: G. K. Allan, late temporary Captain; C. H. Evers, late temporary Captain.

Temporary Lieutenants to be temporary Captains: C. J. C. Macquarie, M. J. Ahern, C. W. Forsyth, R. Stansfeld, J. H. Iles, E. A. D. Maconochie, T. J. Lloyd, G. N. Kirkwood, A. W. Brodribb, G. W. Bury, F. B. Macdonald, P. A. Creux, J. F. H. Stallman, T. Marron.

Temp. Hon. Lieut. W. F. Matthews, of St. John's Ambulance Brigade Hospital, to be temporary honorary Captain.

Temp. Capt. R. H. Lipsey, Canadian Army Dental Corps, reverts to the temporary rank of Lieutenant on attachment to the R.F.C.

To be temporary Lieutenants: F. C. Watson, R. J. MacMillan, A. S. Moorhead, F. Green, S. Spencer, C. Murphy, A. R. P. Scott, J. C. Johnson, G. C. Cossar, P. S. Clarke, F. J. Power, G. Ferguson, R. O'Connor, A. Bryans, H. S. Gabb, W. Crerar, H. Barber, F. Joyce, E. F. Lawson, M. J. O'Flynn, J. M. McCormack, A. G. Heron.

To be temporary honorary Lieutenants: G. H. V. Hunter, H. A. Haskell, C. S. Gilman.

Officers relinquishing their commissions: Temp. Majors: J. C. Briscoe, J. Kerr, W. A. Brend, J. F. Porter, T. M. Martin, F. L. Odlum. Temp. Hon. Major B. Crothers. The undermentioned on appointment under the Ministry of National Service: Temp. Col. J. Galloway, C.B. Temp. Majors: N. S. Manning, W. B. Edwards, A. G. Andrews. Temp. Capts.: H. Owen, J. J. Robb, W. R. Reith, H. Bates, E. L. Jenkins, H. P. Gaston, J. C. Fisher, J. D. C. White, W. G. Gilletley, J. Davies, T. W. E. Moreton. Temp. Lieuts.: C. Alison, W. Johnstone.

Temp. Capts.: J. E. Knox, R. I. Harris, A. R. Riddell, T. C. Routley, J. D. Wilkinson (on account of ill-health contracted on active service) T. J. Simpson, F. Hernaman Johnson (on account of ill-health, and is granted the honorary rank of Captain), C. A. Dupont (on account of ill-health contracted on active service), C. A. Keegan (on account of ill-health), E. T. Jones, J. R. Polson, W. W. Livingston, J. B. Orr, D.S.O., M.C., D. E. Scott. Temp. Lieuts.: H. V. O'Shea, O. H. Woodcock, S. Y. Walsh, J. A. A. Bailey, M. J. Walsh, R. G. Griffin, J. G. Fleming, W. Brennan, A. W. K. Straton.

SPECIAL RESERVE OF OFFICERS.

W. B. Buer to be Lieutenant.

K. J. A. Gillanders, from Glasgow University Contingent O.T.C., to be Lieutenant.

TERRITORIAL FORCE.

Lieut.-Col. (Brevet-Col.) F. H. Westmacott is restored to the establishment.

Major T. A. Barron to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Major (acting Lieut.-Col.) T. A. Barron relinquishes his temporary rank on ceasing to command a Field Ambulance.

Major (acting Lieut.-Col.) A. E. Hodder, D.S.O., relinquishes his acting rank on ceasing to command a Field Ambulance.

Major A. E. Hodder, D.S.O., to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Major A. Milne-Thomson, C.M.G., is seconded whilst holding an appointment as Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Major L. P. Demetriadi resigns his commission on account of ill-health contracted on active service, and is granted the honorary rank of Lieutenant-Colonel.

Major (temp. Lieut.-Col.) G. A. Troup relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. L. A. Rowden, Capt. W. R. Higgins, Capt. R. F. Fagge, Capt. H. H. Markham, and Capt. M. D. Wood are restored to the establishment.

Capt. P. G. Phillips and Capt. C. R. Handfield-Jones resign their commissions on account of ill-health.

Capt. (temp. Major) R. S. Taylor, D.S.O., to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. H. F. Wilkin, M.C., to be acting Lieutenant-Colonel, whilst commanding a Field Ambulance.

Capt. (acting Lieut.-Col.) H. F. Wilkin, M.C., relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (acting Lieut.-Col.) H. B. Low, M.C., relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) A. C. H. McCullagh to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (temp. Major) J. R. Pooler to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. J. P. H. Davies relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

Capt. H. A. P. Robertson, from a Field Ambulance, to be Captain.

Capt. (temp. Major) E. R. Carling relinquishes his temporary rank, and is restored to the establishment.

Capt. P. W. Thompson resigns his commission on account of ill-health contracted on active service, and is granted the honorary rank of Major.

H. J. Shanley, late Captain, R.E. (T.F.), to be Lieutenant.

Cadet G. L. Matthews, from the O.T.C., to be Lieutenant.

To be Captains: Lieut. G. L. Matthews and Lieut. H. J. Shanley.

The undermentioned to be temporary Captains, Hampshire Medical Volunteer Corps: A. E. Clark (late Lieutenant, R.A.M.C.), A. C. D. Newton (late Lieutenant, R.A.M.C.).

Medical Officer and temp. Capt. A. D. Willcocks, from 1st Battalion, to be Medical Officer and temporary Captain, 3rd Battalion, Somerset Volunteer Regiment.

J. McC. McCarthy to be Medical Officer, with the temporary rank of Captain, 1st Battalion, Shropshire Volunteer Regiment.

T. W. Hinds to be temporary Captain, Kent Medical Volunteer Corps.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The November issue of this journal opens with a paper on Skin Diseases and their Treatment under War Conditions, which was read before the Section of Dermatology of the Royal Society of Medicine in April last by Major H. MacCormac. It is well illustrated, four plates being in colours, and deals with a problem which is of considerable importance from the point of view of man-power. Dietetic Fallacies in Connexion with Glycosuria and Albuminuria is the subject of an address by Major Herbert French, and the same issue contains the first part of a Report upon the Bacteriological Examination of One Thousand Soldiers Convalescent from Diseases of the Dysentery and Enteric Groups, by Captain William Fletcher. A joint Preliminary Clinical Report on Trench Fever, by Major W. Byam, Captain Lyn Dimond, Captain V. E. Sorapure, Lieutenant R. M. Wilson, and Lieutenant A. D. Peacock, essays to show that the well-known types of trench fever, with later a stage of slight pyrexia, headaches, anæmia, splenic enlargement, and increased irritability of the nervous system are one disease in succeeding stages, the general unfit man being most susceptible to the development of the chronic type; and, further, that this nervous irritability is the cause of a certain proportion of the D.A.H. cases now arising in France and other theatres of war. Preventive treatment resolves itself into a careful study of the prodromata and the search after means of eradicating the infection before it has gained the upper hand. The authors appeal to other workers to test the value of the various anti-protozoal compounds. "We have some no data as to the value of acriflavine by mouth," they remark, "and one of us, in order to ascertain its effect on the stomach, has taken 10 cubic centimetres of the solution four-hourly for the past six days without being aware of any discomfort."

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. J. N. Griffiths, R.A.M.C., qualified at Sydney, New South Wales, in 1905, and held appointments at the Women's Hospital, Sydney, and at the Public Hospital, Perth, Australia. Later he came to England and practised in Welbeck-street, London, and was honorary assistant physician to the Chelsea Tuberculin Dispensary.

Died of Wounds.

Capt. J. O'S. Beveridge, R.A.M.C., qualified at Dublin in 1915, and joined up shortly afterwards.

Previously reported Wounded, now reported Died of Wounds.

Capt. G. Hislop, R.A.M.C., qualified at Glasgow in 1913, and was in practice at Glasgow prior to joining the R.A.M.C.

Wounded.

Capt. D. A. D. Kennedy, R.A.M.C., attached Rifle Brigade.
Capt. W. J. E. Mingie, Canadian A.M.C.
Capt. H. N. Goode, R.A.M.C.
Capt. L. J Hunter, Australian A.M.C.
Capt. F. H. Cleveland, R.A.M.C., attached Hussars.
Capt. T. R. Kenworthy, R.A.M.C.
Lieut.-Col. T. M. R. Leonard, West African Medical Service.
Lieut. R. A. Hosegood, R.A.M.C., attached Royal Scots.
Capt. A. Stewart, R.A.M.C.
Capt. C. O'Malley, R.A.M.C., attached Middlesex Regiment.

Missing.

Capt. R. T. Bruce, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieut. G. S. Gilbertson, Bedfordshire Regiment, killed in action, second son of Dr. J. H. Gilbertson, of Hitchin, Herts.

Capt. G. R. Nevitt, West Yorkshire Regiment, killed in action, son of the late Mr. J. G. Nevitt, M.R.C.S., of Leeds.

Capt. and Adjt. M. E. Parnell, Indian Cavalry, died of wounds, youngest son of Mr. G. C. Parnell, M.R.C.S., of Forest Hill, London, S.E.

Second Lieut. B. B. Hewat, Royal Field Artillery, killed in action, only child of Dr. M. L. Hewat, of Mowbray, Cape Town, South Africa.

Second Lieut. E. D. Smith, Sherwood Foresters, killed in action, only son of Dr. H. W. Smith, of Pleasley, Mansfield, Notts.

Second Lieut. I. C. Taylor, Royal Scots, killed in action, eldest son of Dr. J. C. Taylor, of Berwick-on-Tweed.

LORD FRENCH'S DESPATCHES.—The volume just issued by Messrs. Chapman and Hall ("The Complete Despatches of Lord French." Price 21*s.* net) in an edition limited to 500 copies, will prove to have historic value. Besides the text of the despatches it contains a complete list of the officers and men mentioned, amongst them no small proportion of the Army Medical Service and Royal Army Medical Corps.

HOSPITAL ACCOMMODATION FOR PENSIONERS.—The Minister of Pensions has appointed a committee including Sir Arthur Newsholme, Mr. J. Smith Whitaker, and Dr. Meredith Richards, with representatives from the War Office, to make a census of hospital accommodation in the country with a view to seeing if it is sufficient to deal with the ex-service men who still require medical or surgical treatment. The first meeting of the committee has been held and a report is expected at an early date.

TRAVELLING MEDICAL BOARDS.—The new Army Council instruction altering the constitution of travelling medical boards directs (1) that the president shall be selected from among the existing presidents or from temporary R.A.M.C. officers who are members of existing boards; (2) that the second permanent member shall be an R.A.M.C. officer selected by the D.D.M.S.; and (3) that the third member shall, in the case of large garrisons, be the commanding officer of a unit not being examined, and in the case of boards which ordinarily visit command depôts or small garrisons a permanent combatant officer (not below field rank) to be appointed by the War Office. The boards will in future undertake reclassification only and have nothing to do with the actual discharge of men from the service.

IMPROVEMENTS IN HOSPITAL ACCOMMODATION IN INDIA.—There are now, including beds for officers, 8115 British war hospital beds, 10,570 Indian war hospital beds, 6480 British convalescent beds, and 13,500 Indian convalescent beds for invalids from field service. Eighteen ocean-going hospital ships have been provided and 11 ambulance (hospital) trains and over 200 motor ambulance cars are now in service in India. Amongst the more notable of the British war hospitals are the Victoria (600 beds), Freeman Thomas (500 beds), Alexandra (618 beds), and the Baroda Hospital for Officers (75 beds), Bombay, the British General Hospital, Deolali (3000 beds), the Deccan War Hospital, Poona (1000 beds), and the Hislop War Hospital, Secunderabad (862 beds). These institutions now compare favourably with hospitals provided at home for casualties from the Western Front.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a meeting of the Royal College of Physicians of Ireland, on Dec. 7th, it was resolved to invite all officers of the U.S. Army Medical Service stationed in Dublin or its neighbourhood to make use of the College library.

ROYAL INSTITUTION.—The following are among the lecture arrangements at the Royal Institution before Easter: Professor Arthur Keith, Fullerian professor of physiology, three lectures on the Problems of British Anthropology; Dr. Leonard Hill, two lectures on (1) the Stifling of Children's Health, (2) the Climatic Adaptation of Black and White Men; Sir R. T. Glazebrook, two lectures on the National Physical Laboratory; Professor William J. Pope, two lectures on the Chemical Action of Light; and Professor Sir J. J. Thomson, six lectures on Problems in Atomic Structure. The Friday meetings will commence on Jan. 18th, when Professor Sir James Dewar will deliver a discourse on Studies on Liquid Films. Succeeding discourses will be given, among others, by Principal E. H. Griffiths and Professor Sir J. J. Thomson.

APPOINTMENTS IN INDIA.—The services of Major L. Cook, I.M.S., are placed permanently at the disposal of the Government of Bihar and Orissa.—Lieutenant-Colonel C. H. James, C.I.E., I.M.S., is appointed to be Professor of Operative Surgery in the Medical College, Lahore.—Lieutenant-Colonel C. H. Bensley, I.M.S., is appointed Inspector-General of Prisons, Central Provinces.

DONATIONS AND BEQUESTS.—The Royal Dental Hospital has received a donation of 100 guineas from Messrs. Barnato Brothers "in memory of the late Mrs. Kate Joel."—The late Mr. George Fisher Melville, Advocate, of Edinburgh and Springfield, North Berwick, who died in July last, left nearly a quarter of a million sterling to be devoted to the "care and cure of cancer" and to research work in connexion therewith. The trust is in the hands of the Dean of Faculty of Advocates, the Deputy Keeper of the Signet, and the Master of the Merchant Company, the present holders of these offices being Mr. James Avon Clyde, Sir George M. Paul, and Mr. Alexander Darling respectively.—The late Mr. P. Vaughan, of Bristol, has bequeathed £6000 to the Queen Victoria Jubilee Convalescent Home, Durdham Downs, Bristol.

THE WANDSWORTH AND DISTRICT NON-PANEL ASSOCIATION.—At a meeting of medical practitioners of the Wandsworth and District Non-Panel Association held on Saturday, Dec. 1st, it was unanimously resolved:—

That the Wandsworth and District Non Panel Association approves and endorses the resolution of the council of the National Medical Union advising its members and all other non-panel medical practitioners to refrain from attending discharged disabled soldiers and sailors under the "special arrangements" of the Insurance Commissioners, but encouraging treatment in their private capacity; and extends this advice to the case of insured patients in hospitals or homes which receive grants from the Ministry of Pensions or the National Insurance Commissioners.

BRIGHTON HOSPITAL SUNDAY FUND.—The result of the Hospital Sunday collections in Brighton, Hove, and district this year surpassed all expectations. Usually £1000 is collected, but on this occasion an urgent appeal was made

that the total might be at least £1200 in view of the demands of the war upon the various institutions. The balance sheet just issued, however, shows that the total realised was £1527 15*s.* 3*d.*, against £1005 8*s.* 4*d.* in 1916. Substantial increased contributions have in consequence been allocated to 13 local medical charities, the Royal Sussex County Hospital receiving £674 as against £432, the Dispensary £183 as against £118, the Queen's Nurses £144 as against £90 10*s.*, the Royal Alexandra Hospital for Sick Children £140 as against £90, and the Women's Hospital £119 10*s.* as against £77, the remaining charities benefiting proportionately.

MEDICAL MAGISTRATE.—The Lord Chancellor has added the name of Mr. Lewis Mackenzie, F.R.C.S. Eng., L.R.C.P. Lond., of Tiverton, on the commission of the peace for the county of Devon.

WORKMEN'S DWELLINGS AT BRISTOL.—The Bristol Town Council has decided to erect 2000 working men's dwellings after the war.

PRESENTATION TO A MEDICAL MAN.—At the meeting of the patients and staff to celebrate the third anniversary of the opening of the V.A. hospital at Newton Abbot, Mr. Richard Henry Grimbly, medical officer in charge, was presented with a silver salver, suitably inscribed, as a mark of respect and gratitude from the nursing and kitchen staff.

BOMBAY WAR AND RELIEF FUND.—The Women's Branch of the Bombay Presidency War and Relief Fund, of which Lady Willingdon is president, gives a satisfactory account of its third year's work. During 1916 donations and subscriptions amounted to more than £23,000, while nearly £58,000 were expended on comforts and materials, and, independently of this, large quantities of gifts in kind were distributed among troops. The administration charges amounted to only 4·5 per cent. Government House was made available for war hospital nurses needing rest, and Mr. Byramjee Jeejeebhoy gave a bungalow at Bandra Point for a similar purpose. From the commencement of the work of the Women's Branch of the Fund the income from all sources has amounted to £129,071, most of which has been disbursed. An appeal for further support will shortly be issued. The beneficent work of the Fund should cause this appeal to meet with an immediate and satisfactory acknowledgment from the central offices of the Fund at Mayo Road, Fort, Bombay.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Health Insurance Bill.

THE National Health Insurance Bill has been passed by one of the Standing Committees of the House of Commons. It was expected that its report stage would be taken early this week, but the arrangements as to business prevented that. During its progress through Committee a number of amendments were made. The provisions of the clause respecting the removal of medical practitioners from panels have been extended, so that chemists may also be disqualified from supplying drugs in certain cases. The first subsection of the clause as amended reads as follows:—

> Where the Insurance Commissioners in pursuance of their powers under Section 15 of the principal Act remove the name of any medical practitioner or of any person, firm, or body corporate undertaking the supply of drugs, medicines, and appliances from any list of medical practitioners prepared under the said section, or from any list of such persons, firms, and bodies corporate as the case may be, they may, if they think fit so to do, remove his or their name from all or any of the other lists so prepared in which it is at the time included, and until such time as the Commissioners direct to the contrary that practitioner or person, firm, or body corporate shall be disqualified for inclusion in any other list, whether in England, Scotland, or Wales, in which his or their name was not then so included, or from which it was then removed.

The following provision respecting the travelling expenses of members of medical committees appears in Clause 41:—

> Any travelling expenses incurred by members of any local committee elected under Subsection (1) of Section 33 of the National Insurance Act, 1913, or of any committee elected by medical practitioners under Section 32 of the said Act in attending meetings of the committee or of any subcommittee thereof, and any expenses incurred by any such members on account of subsistence whilst so attending shall be deemed to be administrative expenses of the committee within the meaning of Subsection (2) of the said Section 33.

Milk for Children and Invalids.

It is explained by Mr. CLYNES, the Parliamentary Secretary to the Ministry of Food, that the Food Controller is aware of the increasing scarcity of milk, but he has no information that in any town invalids and children are finding it impossible to obtain milk. A circular is being issued to Food Control Committees, drawing their attention to their existing powers with regard to giving priority in milk supplies to children and invalids.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 5TH.

Dispensers in Military Hospitals.

Replying to Mr. HOHLER, Mr. MACPHERSON (Under Secretary for War) said: All dispensers employed in military hospitals are required to be qualified under the conditions prescribed in the Standing Orders for the Royal Army Medical Corps. Female dispensers are employed whenever possible and there is no information of any unqualified male dispensers being employed.

THURSDAY, DEC. 6TH.

Midwives (Ireland) Bill.

Answering Mr. MCKEAN, who asked what were the intentions of the Government with respect to the Midwives (Ireland) Bill, Mr. DUKE (Chief Secretary for Ireland) wrote: The second reading of the Bill has been blocked by Irish Members, and there is little hope of the Bill[1] making any substantial progress unless it can be regarded as non-controversial. I am aware of objections that have been raised to some of the provisions of the Bill, but these objections are based on matters of detail which can properly be dealt with in Committee, and I should be ready to consider any amendments that may be proposed in order to remove them.

National Insurance Grants.

Mr. DUNCAN MILLAR asked the Chancellor of the Exchequer whether, having regard to the health requirements of the nation, he was now prepared to sanction the payment of the grant-in-aid for administration and medical benefits, the grant-in-aid for sanatorium benefit, the grants to provide for the expenses of medical referee consultants and of specialist consultants in connexion with medical benefit and the equipment, &c., of clinics, and also the nursing grant, all of which grants had been suspended since the outbreak of war although appearing in the Estimates for National Health Insurance.—Mr. BONAR LAW answered: The suggestion made in the question will be carefully considered in connexion with the estimates of the National Health Insurance Department for the coming year, but having regard to the general financial situation I cannot pledge myself to the revival of all or any of those grants at the present time.

York Practitioners and Treatment of Invalid Soldiers.

Mr. BUTCHER asked the representative of the National Insurance Commissioners whether he was aware that every one of the medical practitioners on the York panel now resident in the area, had refused to attend upon invalid seamen, marines, and soldiers under the regulations recently issued by the National Health Insurance Commissioners (England), but had offered to continue to treat them upon the old (capitation) basis of treatment pending negotiations between the Commissioners and representatives of the medical practitioners, and were at present treating them gratuitously; whether he was aware that the National Health Insurance Commission (England) had refused to allow these persons to be treated upon the capitation basis provided for in the agreements between the Insurance Committee and the practitioners; and what provision was at present made by the National Health Insurance Commission (England) or the York Insurance Committee for adequate medical attention to these insured persons.—Sir E. CORNWALLIS answered: In reply to the first two parts of the question I would refer my honourable friend to the answer to a question on the same subject given on Nov. 26th. On the last part of the question I may say that I am not aware that any insured persons are not receiving adequate medical attendance in the area in question, nor is there any reason why that attendance need be given gratuitously, for the Insurance Committee will pay any bills which are sent up in accordance with the authorised arrangements.

Care of the Blind in Ireland.

Mr. BRADY asked the Chief Secretary for Ireland whether he proposed to set up an advisory committee for Ireland in relation to improvements in the condition of the blind community similar to that being constituted for England and Wales; and what steps had he taken in the matter.—Mr. DUKE replied: I am in communication with the President of the Local Government Board on this subject.

Mr. BRADY: Is the right honourable gentleman aware that a resolution advocating the establishment in Ireland of such a committee was proposed recently by the Protestant Primate of Ireland and seconded by the Catholic manager of a Catholic institution for the blind?—Mr. DUKE: I can assure the honourable Member that full attention is paid to opinion in Ireland on this subject and to the great importance of the matter.

MONDAY, DEC. 10TH.

Panel Practitioners and Invalided Soldiers.

Mr. RAMSAY MACDONALD asked the representative of the National Insurance Commissioners whether he could say

[1] THE LANCET, Dec. 8th, p. 869.

the number of Leicestershire panel practitioners who had notified their respective Insurance Committees that they were not prepared to accept invalided seamen, marines, and soldiers on their lists under the terms of the new regulations.—Sir E. CORNWALL replied: The number of the doctors referred to is not known to me, but at the same time I am not aware of any medical practitioner having refused to render treatment in any such case. I may add that the doctors appear to have been under some misunderstanding in the matter, which a letter from the Commissioners, of which I am sending the honourable Member a copy, will, I hope, serve to remove.

Sir HOWELL DAVIES asked the same questions with regard to Bristol panel practitioners.—Sir E. CORNWALL replied: I am not aware of any medical practitioner in Bristol having refused to render treatment in any such case. I may add that the regulations in question are framed in accordance with the express desires of authoritative representatives of the medical practitioners concerned, and that events subsequent to their issue have shown that the regulations are in fact acceptable to the great majority of such practitioners.

Surgeon Probationers in the Navy.

Dr. MACNAMARA, Secretary of the Admiralty, speaking in regard to a vote dealing with naval personnel, said: As regards medical officers, a number are obtained by the entry of medical students as surgeon probationers of the Royal Naval Volunteer Reserve. These officers are demobilised after a certain time to enable them to complete their medical study, and on being demobilised they are asked if they are willing to re-enter as temporary surgeons when qualified. No compulsion is applied, and their refusal to re-enter does not prevent their being demobilised in the way I have indicated.

WEDNESDAY, DEC. 12TH.

Accommodation in Civil Hospitals.

Sir WM. COLLINS asked the Pensions Minister to state the terms of reference to the committee recently appointed by him to inquire into the accommodation in civil hospitals in Great Britain and the names of those composing the committee; and whether any representatives of the voluntary hospitals were included among the members of the committee.—Sir A. GRIFFITH-BOSCAWEN (Parliamentary Secretary to the Ministry of Pensions) wrote in reply: The terms of reference to the committee recently appointed by me for the survey of institutional accommodation and facilities of treatment in Great Britain are as follows:—

To ascertain the accommodation in civil and other hospitals and institutions (not being Poor-law institutions) for the treatment of sick persons and the facilities available for medical and surgical treatment and care other than that given by general practitioners in Great Britain; to consider, regard being had both to the needs of disabled men discharged from naval or military service and to those of the civilian population, the extent to which, and the means by which, such accommodation and facilities should, if necessary, be increased, and to report thereon at an early date.

The members of the section of the committee which will deal with England and Wales are: Sir A. Griffith-Boscawen (chairman), the Hon. Sir A. Stanley (Red Cross), Sir A. Newsholme (Local Government Board), Dr. J. Smith Whitaker, National Insurance Commission (England), Dr. H. Meredith Richards, National Insurance Commission (Wales), Sir George Bullock and Colonel Webb, R.A.M.C. (War Office), Colonel Sir J. Collie, Sir A. Pearce Gould, and Mr. C. F. A. Hare (assistant secretary to the Ministry). I propose to appoint a separate section of the committee to deal with Scotland. I have considered the desirability of appointing a member to represent the voluntary hospitals, and various names have been suggested to me. I shall be glad to discuss the matter with the honourable Member.

VILLAGE SETTLEMENTS FOR THE CURE AND TRAINING OF DISABLED EX-SERVICE MEN.

Lord HENRY BENTINCK convened a meeting on Dec. 10th in one of the committee rooms at the House of Commons to discuss the proposals, military and civilian, made by the Village Settlements Committee.[1] He pointed out that the number of men and the varieties of disablement were attaining such vast proportions that it was felt by the committee, of which he was a member, that voluntary effort must be put forth in close coöperation with the Ministry of Pensions in order that the problem should be adequately dealt with. A large country house and estate was obtainable where a centre could be started for carrying on both treatment and training. The Ministry of Pensions was not at present in sympathy with this committee's third object—viz., village communities—but fully approved the combining of treatment and training.

Dr. R. FORTESCUE FOX said the committee had three things in view—treatment, training, and settlement. Large numbers of men needed a long period of re-education in good surroundings, and it was essential that the centres for training should not be confined to towns. The Ministry of Pensions was not at present in favour of any permanent grouping of these men, but the permanent village settlement was not immediately in view.

Sir G. BULLOCK objected that disabled men ought not to be kept together except for purposes of treatment.

Mr. WARWICK DRAPER laid great stress on the remedial value of vocational training. The committee hoped to start a metropolitan centre in a carefully chosen site. The Board of Agriculture had promised to provide the necessary training of men able and willing to do agricultural work, and it was hoped that other Government departments would offer help of a like nature. The report, now printed and circulated among those present, had been considered and drawn up with great care.

Lord HENRY BENTINCK said the committee were willing and anxious to consider the joint settlement of disabled and of other discharged men together.

Mr. WARWICK DRAPER added that such settlement as was contemplated was primarily and mainly for the disabled men. The cost of the scheme as suggested would run into at least six figures. No public appeal had as yet been made, but steps were being taken to obtain a grant from public funds available for men injured in the defence of their country. The committee hoped to influence the public, and through it to modify the views of the Ministry of Pensions.

In reply to further questions, Lord HENRY BENTINCK said they proposed to act in good faith in regard to the collection of the necessary funds; and that the importance of placing settlements near suitable industries had been recognised.

Lord SANDWICH deprecated the collecting together of large numbers of men, although some grouping was necessary in order to provide facilities for treatment. Treatment in the cases of mental cripples was often of long duration, and some alternative to stay in hospital was essential.

[1] See THE LANCET, Nov. 3rd, p. 692.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

GRAHAM, R. B., F.R.C.S. Edin., has been appointed in charge of the Craigleith Military Hospital.

HODGE, AGNES J., M.B., C.M. Glasg., D.P.H., Medical Officer of Health for the County of Surrey.

LYONS, R. H., Captain, R.A.M.C., Tuberculosis Medical Officer for Co. Tyrone.

NORRIS, A. H., M.R.C.S., L.R.C.P. Lond., D.P.H., Chairman of the Juvenile Organisations Committee.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BELFAST DISTRICT ASYLUM.—Medical Superintendent of Purdysburn Villa Colony Asylum. Salary £700 per annum.

BIRKENHEAD, BOROUGH HOSPITAL.—Junior House Surgeon. Salary £170 per annum, with board, &c.

BRISTOL EYE HOSPITAL.—House Surgeon, unmarried. Salary £120 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary as arranged, with board, &c.

CHILDREN'S INFIRMARY, Cleveland-street, W.—Female Assistant Medical Officer. Salary at rate of £250 per annum, with board, &c.

DARLINGTON HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

DEPTFORD, METROPOLITAN BOROUGH OF.—Lady Medical Officer, four afternoons a week, for Maternity and Child Welfare Work.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, London, N.—Honorary Medical Officer in Charge of Electro-Therapeutic and Massage Department.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Two House Surgeons. Salary at rate of £100 per annum, with board, &c.

INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary 3 guineas per week and war bonus, with board, &c.

KINGSTON-UPON-HULL, CITY AND COUNTY OF.—Resident Medical Officer. Salary £400 per annum, with board, &c.

LEEDS CITY, PUBLIC HEALTH DEPARTMENT.—Female Medical Assistant. Salary £350 per annum.

LEWISHAM, METROPOLITAN BOROUGH.—Assistant Medical Officer of Health and Maternity and Child Welfare Medical Officer. Salary at rate of £500 per annum.

MANCHESTER ROYAL INFIRMARY (CENTRAL BRANCH).—Resident Surgical Officer. Salary £200 per annum.

NEW HOSPITAL FOR WOMEN, Euston-road.—Female Surgeon for Throat and Ear Department.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician. Salary £200 per annum, with board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Temporary Assistant Physician. Salary at rate of £12 10s. for one attendance per week.

ST. GEORGE'S HOSPITAL.—Senior Assistant and Registrar in Venereal Diseases Department. Salary at rate of £250 per annum.
SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Senior House Surgeon. Salary £300 per annum, with board, &c.
STOKE-ON-TRENT, COUNTY BOROUGH.—Female Assistant Medical Officer. Salary £350 per annum.
WALSALL AND DISTRICT HOSPITAL.—Female Senior House Surgeon. Salary £250 per annum, with board, &c.
WEST HAM UNION INFIRMARY, Whipp's Cross-road, Leytonstone, E.—Temporary Assistant Medical Officer. Salary £300 per annum.
WILLESDEN URBAN DISTRICT COUNCIL, HEALTH DEPARTMENT.—Temporary Assistant Medical Officer. Salary 10 guineas per week.
THE Chief Inspector of Factories, Home Office, S.W., gives notices of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Kenilworth, Warwick; Killeshandra, Cavan; Wolsingham, Durham; and at Yarmouth, Isle of Wight.

Births, Marriages, and Deaths.

BIRTHS.

HEWLETT.—On Dec. 4th, at "Sunnycroft," Crawley Down, to Professor and Mrs. R. Tanner Hewlett—a son.
MICKLEM.—On Dec. 9th, at Northridge, Boxmoor, the wife of Thomas Esmond Micklem, M.B., Lieutenant, R.A.M.C., of a son.
SEQUEIRA.—On Dec. 5th, at Charlton-terrace, Plymouth, the wife of Fleet-Surgeon W. S. H. Sequeira, R.N., of a daughter.
SMYTHE.—On the 7th Dec., at 28, St. George's-terrace, Trowbridge, Wilts, the wife of Captain Gerald Smythe, M.B., B.C. Camb., R.A.M.C., of a daughter.
SOLOMONS.—On Dec. 9th, at Fitzwilliam-square, Dublin, the wife of Bethel Solomons, M.D., F.R.C.P.I., of a son.

MARRIAGES.

COOK—REID.—On Dec. 4th, at St. Edmund's Church, Mansfield Woodhouse, Frank Cook, Captain, R.A.M.C. (S.R.), to Sister Edith H. W. Reid, youngest daughter of the late Rev. James Reid, of Co. Cork, Ireland.
GARRATT—TROTMAN.—On Dec. 5th, at the Catholic Cathedral, Brentwood, Essex, Captain Frank Garratt, R.A.M.C., to Winefride Mary, younger daughter of Mr. J. W. and the late Mrs. Trotman, of "Bromsgrove," Brentwood, Essex.
MOORE—GRANT.—On Dec. 7th, at Holy Trinity Church, Broadstairs, Leslie Moore, Lieutenant, R.A.M.C., to Marion, second daughter of the late Lieutenant-Colonel Grant, of Sunbury-on-Thames, and Mrs. Grant, Thicket Lodge, Broadstairs.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

MEDICAL INVENTORS.

MEDICAL men, especially surgeons, as would be expected, have invented many new instruments and much new apparatus to assist them in their operative work. But it is not widely known that medical men have often been the originators of inventions for general or lay use. Thus Charles Brooke (1804–79), one of the first Cambridge graduates to become F.R.C.S.—twenty-third Wrangler in 1827—invented not only the "bead suture," which marked a step forward in the treatment of deep wounds, but also the exquisite self-recording instruments now in use in all important astronomical observatories. The famous James Syme, whose character Dr. John Brown summed up as "verax, capax, perspicax, sagax, efficax, tenax," may be termed the father of "the mackintosh," in that he was the inventor of waterproofing, the garment being courteously called after a famous clan in his native land, where its uses are perpetual. James Startin (1806-72), F.R.C.S., made an important commercial discovery when as a youth he was studying his profession in the laboratory of Mr. Chawner, of Atherstone, to whose firm he was apprenticed. This discovery was the process of stiffening felt hats. To Startin, therefore, we may be said to owe the useful, though ugly, bowler hat. *Papier-maché* and plaster-of-Paris are also, we believe, the inventions of medical men. But perhaps the most distinguished inventor of a surgical appliance, afterwards turned to world-wide commercial and domestic account, was William Rawlings Beaumont, F.R.C.S., M.D., of Toronto. His instrument for making deep sutures, first used in 1837 by Lawrence when operating on a cleft palate, was believed to have suggested the sewing-machine to Singer. "If it be true," said Sir James Paget, "that the sight of this instrument in the window of an instrument-maker in New York suggested the invention of the Singer sewing-machine, we might regret that mechanical ingenuity should gain so much less money in surgery than in trade."

These remarks have been prompted by a piece of information, rather in the nature of a question put to us by a correspondent in the following terms:—Thomas Michael Greenhow (1792–1881), F.R.C.S., was a man of great mechanical ingenuity and constructed various instruments and modifications of surgical appliances which his long experience at the Newcastle Infirmary suggested to him. But besides his well-known "fracture-bed" of date 1833 he made models of machines of various kinds unconnected with his surgical practice, and was busy with these lay inventions up to the close of his long life. One would like to know more about them, for they are presumably extant.

It would be interesting to know what the late T. M. Greenhow actually invented. He was a man of great ingenuity and not likely to have spent his time in futile experiment. Perhaps someone can enlighten our correspondent.

WHAT'S IN A NAME?

IN the third number of an excellent *Journal of the Department of Public Health*, issued in Wellington by Hon. G. W. Russell, Minister of Public Health, is an article on "Twilight Sleep," which the Journal states is as well known to the medical profession in New Zealand as elsewhere. The experience is given of various St. Helens hospitals, which may be summed up in a sentence: "We still use it in many cases, but not so generally as formerly. It is not without risks, especially to the infant, and is not in favour with the ordinary practitioner on that account." The conclusion drawn is that whilst, generally speaking, little or no ill-effects result to the mother from the use of the drug, yet for the sake of the baby the mother should make an endeavour to submit to some of the pains of labour under natural conditions. The popularisation of the treatment is attributed to its alluring title. Would "Twilight Sleep" have gained any popularity, the question is asked, if it had been termed "The Dope Delivery Method," or the "Half-dead Baby System"?

SURGERY IN JERUSALEM OVER 3000 YEARS AGO.

To the Editor of THE LANCET.

SIR,—The news of the capture of Jerusalem by General Allenby reminds me that in the first chapter of Judges it is stated that Judah fought against the Canaanites and the Perizites and smote of them in Bezek in Palestine 10,000 men. And they found Adoni-bezek (the Lord of Bezek) in Bezek: but he fled, and they pursued after him, and cut off his thumbs and his great toes. And Adoni-bezek said, "Three score

and ten kings, having their thumbs and their great toes cut off, gathered their meat under my table: as I have done, so God hath requited me. And they brought him to Jerusalem, and he died there." This seems to imply that although the surgical operations had been successful in the case of the 70 kings who lived to eat meat, it was unsuccessful in the case of Adoni-bezek, and that he died therefrom. I do not know if there is a term describing this operation, but I suppose it would be called "wholesale pollectomy." It was evidently a routine practice, and must have prevented a man holding a weapon or running away. I am, Sir, yours faithfully,

Dec. 11th, 1917. SALEM.

*** According to Ælian, in after ages, the Athenians, at the instigation of Cleon, son of Cleænetus, made a decree that all the inhabitants of the island of Ægina should have the thumb cut off from the right hand, so that they might ever after be disabled from holding a spear, yet might handle an oar. It was a custom among those Romans who did not like a military life to cut off their thumb that they might be incapable of serving in the army; and for the same reason parents sometimes cut off the thumbs of their children.—ED. L.

PARAFFIN IN THE TREATMENT OF WOUNDS.

As a result of extensive comparative observations, Professor Giovanni Masnata, at present in charge of the military hospital at Stradella (Pavia), concludes that paraffin of melting point 50–52° C. is as efficacious as ambrine in the treatment of wounds. His results appear in detail in *Il Policlinico*, vol. xxiv., C., 1917.

A CURIOUS ACTION OF MERCURY ON ALUMINIUM.

To the Editor of THE LANCET.

SIR,—Some years ago I also had the curious experience of witnessing this thing that Dr. Cameron Kidd relates in THE LANCET for Nov. 24th. I was working with mercury and accidentally placed an excess of the Hg in the aluminium cap of a bottle. I went on with my work and in a few minutes afterwards my attention was arrested by the peculiar behaviour of the aluminium lid: the lid was visibly sprouting a fine growth of white "worms" in a dozen different directions. One could *see* them growing outward and falling off. I demonstrated it to many people, including chemists, but I do not think any of them understood the reason why. I see your consulting chemist has confirmed these interesting observations. I have performed the experiment in the absence of breathing and moisture—i.e., in a dry heat—so the explanation must be sought in another direction. It is very interesting.

I am, Sir, yours faithfully,

M. H. FLEMING, Captain, R.A.M.C.

Biscot Camp, Luton, Beds, Dec. 3rd, 1917.

JUVENILE CRIME.

WE have received a letter, signed by Lord Lytton and other officers of the State Children's Association (53, Victoria-street, London, S.W.), lamenting the practice of sending to prison boys between the ages of 15 and 18. For these our present prison system is, they state, never reformative, and imprisonment is unnecessary in view of the alternative system of probation which the justices have employed in some London and provincial courts with admirable effect. Numbers of young persons so dealt with after a probationary term make no further appearance before the justices. The letter therefore appeals to men and women possessing sympathy with and understanding of the young to offer their services to the local benches of magistrates as voluntary probation officers for one, two, or more children. Under the influence of a steadying friendship a great number of the juvenile offenders of to-day may well become trustworthy citizens of to-morrow.

FIRE PREVENTION AT CHRISTMAS.

WITH the near approach of Christmas, and its increased dangers from fire, particularly in hospitals and other places where entertainments are given, the British Fire Prevention Committee (8, Waterloo-place, London, S.W. 1) have again issued a Christmas entertainments fire-warning sheet, No. 22A, showing what should be done to lessen the risk and to cope with an outbreak of fire if it occurs. 10,000 copies of the sheet are being exhibited throughout the country, and a single copy will be sent upon written application enclosing a stamped envelope.

Civil Medical Practitioner refers with justice to the fact that it is easier for his class to obtain unpaid than paid military work. The Central Medical War Committee welcomes the names of practitioners who are willing and able to relieve their juniors in civil practice.

Transcriber's Gloss.—The R.A.M.C. orderlies who are charged with much of the transcribing incident on medical case-taking as a rule do well, but a correspondent sends us an entry—"chronic *intestinal* nephritis"—which was at first sight puzzling

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Dec. 18th.

GENERAL MEETING OF FELLOWS, at 5 P.M.

Ballot for Election to the Fellowship. (Names already circulated.)

MEETINGS OF SECTIONS.

Wednesday, Dec. 19th.

HISTORY OF MEDICINE (Hon. Secretaries - J. D. Rolleston, Charles Singer): at 5 P.M.

Exhibition of Pictures, Books, &c. (at 4.30 P.M.).

Papers:

Dr. G. C. Peachey: The Two John Peacheys, Seventeenth Century Physicians: their Lives and Times.

Dr. C. G. Cumston: (1) Morgagni and the Foramen Cæcum; (2) The Death of King Henry II. of France, with a rare engraving of the event.

Thursday, Dec. 20th.

DERMATOLOGY (Hon. Secretaries—J. E. R. McDonagh, H. MacCormac; Acting Hon. Secretary—S. E. Dore): at 5 P.M.

Cases will be shown.

Friday, Dec. 21st.

ELECTRO-THERAPEUTICS (Hon. Secretaries—E. P. Cumberbatch, Robert Knox): at 8.30 P.M.

Paper:

Mr. A. E. Baines: On the Interpretation of Certain Electro-Physiological Phenomena.

ROYAL STATISTICAL SOCIETY, at the Surveyors' Institution, 12, Great George-street, S.W. 1.

TUESDAY.—5.15 P.M., Paper:—Sir R. Henry Rew, K.C.B.: The Prospects of the World's Food Supplies after the War.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—4.30 P.M., Prof. J. W. Anderson: Science and the Cold Storage Industry.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W. 1.

WEDNESDAY.—8 P.M., Paper:—Prof. W. Bateson: Cytology and Genetics.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—5.30 P.M., Paper:—Col. J. H. T. Walsh, I.M.S. (retired): The Geographical Distribution of Human Diseases and their Control.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

THE address of the Australian Red Cross Society is now 36, Grosvenor-place, London, S.W. 1.

MANAGER'S NOTICES.

TO SUBSCRIBERS IN THE UNITED STATES.

Messrs. Wm. Wood and Co., of New York, are relinquishing their Agency for the supply of THE LANCET in the United States at the end of the present year. The Manager of THE LANCET will be pleased to supply copies direct from the London Office to subscribers in the United States at the strictly prepaid rate of $8 for twelve months. Subscriptions may commence at any time. Drafts and Money Orders should be made payable to the Manager, Mr. CHARLES GOOD, 1, Bedford-street, Strand, London, W.C. 2, England.

TO SUBSCRIBERS.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on advertisement page 8.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

"MALTINE"

"Maltine" presents the proteids, carbohydrates, and organic phosphates of malt in an agreeable, convenient, and readily assimilable form. It is standardised in diastase, concentrated, and semi-liquid, and perfectly soluble.

Special Indication:—

In Infant Feeding, to humanise cow's milk and prevent constipation.

Full particulars, together with complete Feeding Tables, giving the proportions of milk and water for different ages and periods of feeding, as also samples of "MALTINE," may be obtained free of charge by Medical Men on application to the Company.

"MALTINE" WITH IRON.

Each Fluid Ounce contains—IRON PYROPHOSPHATE ... 8 grains.

This is a particularly bland and assimilable preparation of Iron, in which the astringency of the ferruginous salt is counteracted by the slightly laxative action of the "MALTINE" base.

"MALTINE" WITH COD LIVER OIL

is a complete, physiologically proportioned food, containing all the elements of nutrition in easily assimilated form, possesses valuable diastasic power, and is distinguished by its Palatability. *The British Medical Journal* states: "Apart from its own dietetic value, 'Maltine,' when combined with Cod Liver Oil, certainly enables the latter to be taken by persons who can neither swallow nor assimilate it in any other form."

The word "MALTINE" is our Trade Mark.

In prescribing kindly specify "MALTINE COMPANY."

THE MALTINE MANUFACTURING CO., Ltd., 183, Acton Vale, London, W. 3,

Will be pleased to send Samples Free of Charge to Medical Men.

CARNRICK'S "LIQUID PEPTONOIDS."

Beef, Milk, and Wheat (Pre-digested).

"LIQUID PEPTONOIDS" is a sustaining, reconstructive, mildly stimulating fluid nutrient, ready for immediate absorption and assimilation. It is aseptic, eminently palatable, free from extractive material, completely pre-digested, and sufficiently concentrated to nourish a patient for a considerable time during critical stages of severe illness when other forms of food are refused.

Samples Free to Medical Men.

CARNRICK & CO., Limited, 183, Acton Vale, London, W. 3.

"Science is, I believe, nothing but trained and organized common-sense, differing from the latter only as a veteran may differ from a raw recruit: and its methods differ from those of common-sense only so far as the Guardsman's cut and thrust differ from the manner in which a savage wields his club."

Professor Huxley.

The Basis of Science

BOOTS PURE DRUG COMPANY LIMITED wish to draw the attention of the medical profession to the following seven scientific preparations. Practitioners who endeavour to keep abreast of the times will find these modern antiseptics of superlative value in general practice.

CHLORAMINE-T

(p-toluene-sodium-sulphochloramide).

Dakin's ideal antiseptic, of wide applicability in medicine and surgery.

In bottles of 1oz., **1/2**; 4oz., **3/6**; 1lb., **12/6**

CHLORAMINE-T GAUZE

In two strengths, containing approximately 5% and 35% Chloramine-T. (5% supplied unless otherwise specified). This should be fixed dry and subsequently moistened, if necessary, when in position.

In sealed packages only, price **1/-** per package.

PROFLAVINE

(3·6 diamino-acridine-sulphate).

The improved Flavine derivative.

Equal in antiseptic powers to ***Acriflavine***, and in important respects superior, being markedly less toxic and less irritating. Proflavine, being less costly to manufacture, can be sold at a substantially lower price than Acriflavine.

5 gram bottle, **1/4**; 20 gram bottle, **5/-**

TABLETS OF CHLORAMINE-T

One tablet dissolved in two ounces of water makes a one per cent. solution.

Bottles of 50, 8·75 grain tablets, **2/-**
" " 100, " " " **3/9**

One tablet dissolved in ten ounces of water makes a one per cent. solution.

Bottles of 12, 43·75 grain tablets, **1/10**

CHLORAMINE-T CREAM

Containing approximately one per cent. Chloramine-T. Described and investigated under the name of Chloramine Paste by Vincent Daufresne, Carrel, Hartmann and others, in the *Journal of Experimental Medicine*, 1917.

In Pots. Trial size, **9d.**; large size, **2/6.**

TABLETS OF PROFLAVINE

(with sodium chloride).

One tablet dissolved in four fluid ounces sterile water makes 1:1000 Proflavine in normal saline.

Bottles of 100 tablets, **3/6**

HALAZONE TABLETS.

DAKIN'S NEW WATER DISINFECTANT.
Vide B.M.J., May, 1917.

The action of Halazone is positive, and may be relied upon for crudest waters. Each tablet is sufficient to sterilize one quart of contaminated water, but in cases of extreme contamination a second tablet may be necessary. Halazone is invaluable for those on active service overseas, more particularly in hot climates.

Bottles of 100 tablets, **6d.**

Supplies are available for prescription service on application through any of the branches of BOOTS THE CHEMISTS.

Boots Pure Drug Company Limited

MANUFACTURING CHEMISTS AND MAKERS OF FINE CHEMICALS.

Head Offices: Station Street, Nottingham. JESSE BOOT, Managing Director.

RICKETS AND CHILD WASTAGE

Rickets claims a foremost place among the ravages of childhood.

Professor G. F. Still, in his well-known work on "Common Disorders and Diseases of Childhood," says:—

> "Rickets is one of the commonest disorders of early life amongst the poorer populations of large cities, nor is it very rare in its slighter manifestations amongst the well-to-do, and yet there are few diseases which are more easily preventable."

The causation of Rickets is still a subject for discussion. It is mainly due to inappropriate food. Some theorizers have suggested that the use of Dried Milk may lead to the production of rickets. There is no evidence that this is so, provided that a proper form of dried whole milk is employed.

The evidence goes to show that Dried Milk of reliable quality and given in a suitable form under hygienic conditions acts as a valuable preventive of rickets. Much reliable evidence has been collated by Dr. J. E. Lane-Claypon, late Assistant Medical Inspector under the Local Government Board, and published in "Milk and its Hygienic Relations" recently issued under the direction of the Medical Research Committee of the National Health Insurance Commission.

The following quotations merit consideration:—

> "The general experience, however, which has now been gained as a result of the large infant welfare centres in this and other countries has tended to discredit any belief in the production of rickets by the use of boiled milk."

The experience of Dr. Naish is quoted:—

> "I have followed up considerable numbers of those fed on dried milk, and noted the time at which independent walking commences; this I have found to be usually within fourteen months, except where the infant has been very far from the normal at the time of its first attendance or has suffered subsequently from measles, whooping-cough, or other bacterial infection; in not a few cases the child has walked before the end of the first year and in one case at nine months. I have also followed up as many as possible to the ages of three, four, and five years, and am personally convinced that there is no more risk of rickets with this diet than with a good quality raw cow's milk."

Dr. Naish is of opinion that it is possible to cure rickets by putting the young patient on a dried milk diet.

Dr. J. Lane-Claypon states dogmatically that

> "There is no evidence to show that the use of heated milk is productive of rickets in young children."

Extensive experience with GLAXO shows that with a reliable dried milk there is not only no danger of producing rickets, but that where a child is on an unsuitable food and is suffering from digestive disturbances, and is becoming the subject of malnutrition, the surest way to correct disorder and prevent the development of rickets and other morbid states is to administer dried milk systematically.

GLAXO is the most reliable form of dried milk. GLAXO is pure cows' milk and contains nothing but the ingredients of milk. It is enriched with cream and milk sugar, and then dried by the Glaxo special process which renders it more digestible than ordinary milk.

Samples and full particulars will be sent to any Medical Practitioners in Great Britain and Ireland, and in Britain Overseas on application.

THE STANDARDISED DRIED MILK.

GLAXO (Medical Dept.), 155, Great Portland Street, London, W. 1.

Proprietors: Joseph Nathan & Co., Ltd., London and New Zealand.

A SUGGESTION.

Send us a Post-card for Samples of LACTOPEPTINE to prescribe in a case of Flatulent Dyspepsia or Infantile Diarrhœa.

1. No one has successfully imitated the digestive value of Lactopeptine.

2. Lactopeptine is an ideal digestive remedy which commends itself to every Medical Practitioner on account of its uniformity of action, published formula, and extreme palatableness. :: :: :: ::

3. Lactopeptine is one of the certainties of Medicine, and in this respect ranks with quinine. :: :: :: :: :: ::

4. INDICATIONS: Dyspepsia, Infantile Diarrhœa, Acute Indigestion, Morning Sickness, Impaired Nutrition, Flatulent Dyspepsia. :: ::

When prescribing, specify in all cases Lactopeptine (Richards).

Supplied in ½ oz., 1 oz., 4 oz., and 8 oz. bottles.

John Morgan Richards & Sons, Ltd., 46 Holborn Viaduct, London, E.C.

LACTOPEPTINE

POWDER TABLETS, ELIXIR

Antikamnia Tablets

AK

Strongly Recommended in:

INFLUENZA & LA GRIPPE

AK

For the headache, pain, and general soreness give a five-grain Antikamnia Tablet crushed with a little water; if the pain is very severe two tablets should be given. Repeat every 2 or 3 hours as required. One single ten-grain dose is often followed by complete relief.

NEURALGIA

In the Treatment of Neuralgia and Myalgic Pains Antikamnia Tablets are not only palliative, but, along with other measures, assist in ultimate cures; they also have a field of use in Rheumatic and Gouty Affections. In Neurasthenia, Hysteria, and Migraine they are a valuable adjuvant to the other recognised therapeutic measures.

LARYNGEAL COUGH

AK

Frequently remains after an attack of La Grippe, and has been found stubborn to yield to treatment. There is an irritation of the larynx, huskiness, and a dry and wheezing cough, usually worse at night. The prolonged and intense paroxysms of coughing are controlled by **ANTIKAMNIA & CODEINE TABLETS**, and with the cessation of the coughing the laryngeal irritation subsides.
Antikamnia Tablets are the least depressing of all the drugs that can exercise so extensive a control of pain, and also least disturbing to the digestive and other organic functions.

Analgesic. Antipyretic. Anodyne.

Antikamnia Preparations in 1-oz. packages only.

JOHN MORGAN RICHARDS & SONS Ltd.,

46-47, Holborn Viaduct, LONDON.

HOMMEL'S HÆMATOGEN

A natural organic IRON TONIC associated with nourishing albuminous proteids.

Entirely Free from Antiseptics.

AN EFFICACIOUS REMEDY IN SEVERAL FORMS OF ANÆMIA, associated with constitutional diseases, and A POWERFUL RESTORATIVE when much blood has been lost, as from wounds sustained in action, by post-partum hæmorrhage, or in the course of surgical operations.

IMPROVES THE GENERAL NUTRITION IN TUBERCULOSIS.

PALATABLE, APPETISING, and free from any constipating tendency.

☛ **Please note that HOMMEL'S HÆMATOGEN is and always has been manufactured in SWITZERLAND BY SWISS PROPRIETORS, and that a continuous supply is assured. The price has not been increased.**

In prescribing please always specify HOMMEL'S Hæmatogen.

First Class Award for Liquors and Liquid Extracts and Pharmaceutical Preparations International Medical Exhibition, London, '81.

Battley's Liquors

First Class Award at World's Industrial Exposition, New Orleans, 1885, Bronze Medal, St. Louis, 1904.

The following preparations have for many years been used and prescribed by medical men; they are therefore thoroughly recommended both on account of their high therapeutical properties and their great purity as galenical preparations.

Liquor Opii Sedativus (Battley)

Dose: 5 to 15 minims.

The Oldest and still the Best Hypnotic and Sedative. Twice the strength of Tinctura Opii B.P. Safe in use. No disagreeable after effects. Composition always reliable.

Liquor Cinchonæ Cord. (Battley)

Dose: 2 to 15 minims.

The most reliable preparation of Cinchona Bark. Contains all the active principles of Yellow Bark. Will remain unaltered for a great length of time, being free from starch, etc.

Liquor Cinch. Pallidæ (Battley)

Dose: 2 to 15 minims.

A well-known and useful preparation in Malarial Diseases and in Convalescence after Illness. Does not disturb the stomach.

Liquor Secalis Cornuti (Battley)

Dose: 20 to 60 minims.

Pre-eminent among Ergotic Preparations for Purity and Strength, and has proved to be unrivalled in the following therapeutical actions:—As an Emmenagogue and Ecbolic, in Post Partum Hæmorrhage, as a Hæmostatic, etc.

Battley's Liquors are issued in 2 oz., 4 oz., 8 oz. and 1 lb. bottles.
They are prepared according to the original process of the late Richard Battley.

Ditto Chest piece (Fig. B.) 7/6

Ditto Single flexible (Fig. C.) 9/9

Ditto Double flexible (Fig. D.) 13/6

Ditto Binaural (Fig. E.) 16/6

Ditto Folding (Fig. F.) 17/6

COPIES OF UNSOLICITED TESTIMONIALS.

DEAR SIRS,—"I find that most certainly the chest sounds are rendered clearer and more distinct by your 'Phonophore' than by any stethoscope I have used during over thirty years' work."—Yours, F.R.C.S.

DEAR SIRS,—"I may say I am very pleased with the Phonophore. It renders chest sounds more audible and more distinct than any instrument I have so far used."—Yours faithfully.

DEAR SIRS,—"I have used the Phonophore for twenty years, and have never come across a better stethoscope."—Yours faithfully.

Extract from the "British Medical Journal":—"Some years ago Messrs. Arnold & Sons, of Giltspur-street, E.C., brought out a Stethoscope which they named the 'Phonophore.' Its construction secured a considerably increased volume of sound, and the appliance gained favour among those dissatisfied on general grounds with ordinary stethoscopes, or whose needs, owing to some lack of aural acuity, were not adequately met thereby. Of this appliance the same firm has recently brought out a modification in which the bell-like attachment constituting the chest-piece is provided with two sound tubes instead of one. These tubes are continued upwards, the sound thus being conveyed to each ear direct from the collecting chamber. The gross volume of sound is also greater than supplied even by the original 'Phonophore.' This modification of the 'Phonophore' is worth examination by anyone interested in stethoscopy."

"PANCROBILIN" REED & CARNRICK

(NUCLEO-ENZYMES OF THE PANCREAS WITH DEHYDRATED BILE)

INCREASES THE FLOW OF BILE AND ACTIVITY OF LIVER, PREVENTING THE FORMATION OF GALL-STONES.

Many cases of constipation grow worse under the continued use of cathartics and purges. The normal stimulant to the intestines is found in the pancreatic juice and the bile. PANCROBILIN is composed of the nucleo-enzymes of the pancreas with dehydrated bile. The nucleo-enzymes of the pancreas are more active and truer to Nature's secretion than pancreatin. So dehydrated bile is better than the ordinary bile salts, because the water has been removed without the use of high heat, which changes the nature of the bile as it normally exists; consequently PANCROBILIN is more effective than the usual combinations of pancreatin and desiccated bile.

Original bottles of 100 gelatine-coated small pills for dispensing.

ORAL SEPSIS.

"EUMENTHOL JUJUBES"

(HUDSON).

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics, Eucalyptus (a well-rectified Oil free from aldehydes (especially valeric aldehyde), which make themselves unpleasantly noticeable in crude oils by their tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., they exhibit the antiseptic properties in a fragrant and efficient form. Non-coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

THE LANCET says:—

"In the experiments tried the Jujube proved to be as effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S.,
Public Analyst of Sydney, after making exhaustive tests, says:—

"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth. ..... I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

THE PRACTITIONER says:—

"They are recommended for use in cases of oral sepsis, a condition to which much attention has been called in recent years as a source of gastric troubles and general constitutional disturbance, and are also useful in tonsillitis, pharyngitis, &c."

The AUSTRALASIAN MEDICAL GAZETTE:

"Should prove of great service."

KEROL

KEROL combines all the properties which go to the making of an ideal preparation.
It has been shown to be practically non-toxic, non-irritant and non-corrosive—a combination of properties which make it the one preparation which can be used with perfect confidence wherever the use of either a disinfectant or antiseptic is indicated. It is of high and definite germicidal value and is perfectly homogeneous

KEROL is highly recommended by Bacteriologists and by prominent members of the Medical Profession.

KEROL CAPSULES

INTESTINAL. These are of great value where intestinal antisepsis is indicated. In a comparatively short space of time the coli content of the intestine is reduced by over 99 per cent. They are non-irritant and perfectly safe

STOMACHIC. For use in cases of stomach fermentation and other gastric troubles, and are of great value in reducing the number of malign organisms prior to administration of treatment with lactic ferments, i.e., sour milk, etc.

BLENOSAN
CAPSULES

As a routine
treatment for

GENITO-URINARY CONDITIONS.

BLENOSAN is a mixture of the finest East India Santal Oil with a specially prepared fluid extract of Kava-Kava. It is presented in the form of accurately-measured Capsules, and affords an ideal medicament for the treatment of all inflammatory conditions of the urethra.

BLENOSAN is an improvement upon the ordinary Santal, and the full proportion of the alpha resin of Kava-Kava ensures all the anæsthetic and diuretic properties of the root in a standardised and dependable form.

BLENOSAN CAPSULES consequently are indicated in all pathological conditions which affect the genito-urinary system, including acute Cystitis, Vaginitis, and Leucorrhœa, and where intense hyperæmia and swelling of the mucous membrane give rise to a diminution of the urinary canal.

BLENOSAN CAPSULES are well adapted for the continuous and systematic treatment of such cases, and are being used with excellent results by many of the most experienced and successful Physicians.

BLENOSAN CAPSULES can be prescribed for a course of treatment extending over two or three weeks.

VALE OF CLWYD SANATORIUM

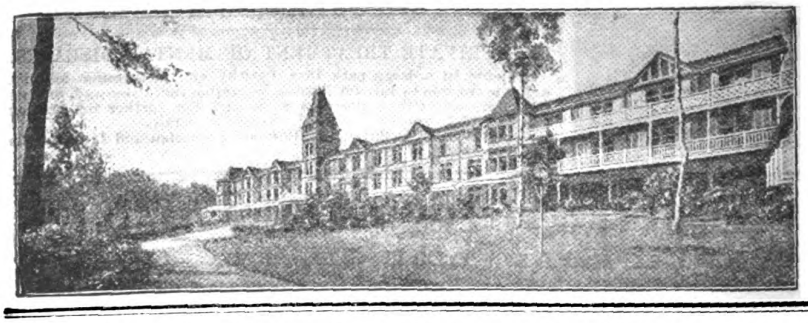
This Sanatorium (opened 1901) is established for the Treatment of Tuberculosis as carried out by Dr. OTTO WALTHER of Nordrach. It is situated in the midst of a large area of park-land, at a height of 450 feet above the sea-level, on the western slopes of mountains rising to over 1800 feet, which protect it from North and East winds and provide many miles of carefully graduated uphill walks—similar in character and extent to those at Nordrach.

Small rainfall. Porous subsoil. Large amount of sunshine. Electric Lighting and Hot Water Radiators in each room.

The physician himself was a patient at Nordrach.

For particulars, apply to GEORGE A. CRACE-CALVERT, M.B., &c., Llanbedr Hall, Ruthin, North Wales

DUFF HOUSE, BANFF, SCOTLAND.



TREATMENT OF DISORDERS OF THE STOMACH AND INTESTINES, DIABETES, GOUT,

and other complaints which need skilled chemical investigation and dietetic treatment.

The House is fitted with Laboratories, X-Ray Installation, Medical Baths, and Lifts.

The climate is mild, and the rainfall the lowest in Scotland.

Apply,
The Secretary,
Duff House,
Banff.

A NEW METAL TOURNIQUET

(PATENT APPLICATION No. 1588/17.)

ADVANTAGES:

Ease of application.
Ease and simplicity of adjusting force of constriction.
Accuracy of adjustment — preventing excessive pressure and permitting early relief.
Imperishable—even in the hottest climate.
Easily sterilized.
Packs into small space.

A DEFT AND RELIABLE ASSISTANT TO THE HARD-PRESSED SURGEON.

In the course of an article in the "Journal of the Royal Naval Medical Service" for April, 1917, Temp. Surg.-Gen. Lenthal Cheatle, C.V.O., C.B., F.R.C.S., R.N., says: "I have confidence in recommending this instrument. I was convinced that a properly designed and manufactured tourniquet of metal would be superior to all instruments in use for the same work. The design fulfils all my expectations."

Write for particulars to the Sole Makers:

JOHNSON AND PHILLIPS LTD CHARLTON, LONDON, S.E.

A Government Decree

Soldiers, Sailors, and Airmen—by Government decree—wear pure wool next the skin. Medical opinion upholds this command—the health of the men proves its wisdom.

For fifty years doctors have advised Wolsey because it is *pure wool*. To-day, though wool is scarce and dear, Wolsey remains pure wool — untampered with, uncheapened in its quality. Forced upwards by the increased cost of wool, the price of Wolsey has risen. But Wolsey is worth its extra cost.

Wolsey

Pure Wool Underwear

The Wolsey machidery is busily engaged in making underwear for the troops—their urgent needs come first. Wolsey should now be ordered in advance to ensure supply. Wolsey garments are made for men, women, and children. Any garment found to shrink is replaced free of cost.

THE WOLSEY UNDERWEAR COMPANY, LEICESTER.

PRINTED and PUBLISHED by the PROPRIETORS, WAKLEY AND SON (1912), LTD., at No. 423 Strand, and Nos. 1 and 2, Bedford-street, adjoining, in the County of London.—Saturday, Dec. 15th, 1917.

SAUNDERS' BOOKS

Albee's Bone-Graft Surgery

SECOND PRINTING

In this work you get for the first time all Dr. Albee's successful technic and its practical application. You get a full and clear description of his electric motor operating outfit and the technic of its use—illustrated. The section on fractures covers 100 pages and contains 100 illustrations.

Octavo of 417 pages, 332 illustrations, 3 in colours. By FRED H. ALBEE, M.D., Professor of Orthopædic Surgery, New York Post-Graduate Medical School. Cloth, 28s. net.

Elsberg's Surgery of the Cord

DIAGNOSIS & TREATMENT

This book gives you in clear definite language the diagnosis and treatment of all surgical diseases of the spinal cord and its meninges, illustrating each operation with original pictures. It goes thoroughly into symptomatology, diagnosis, and indications for operation and actual technic. The first part is devoted to anatomy and physiology of the spinal cord.

Large octavo of 330 pages, with 158 illustrations, 3 in colours. By CHARLES A. ELSBERG, M.D., Professor of Clinical Surgery, New York University and Bellevue Hospital Medical School. Cloth, 21s. net.

Faught on Blood Pressure

SECOND EDITION

The *second edition* of this work has been enlarged by 200 pages. There have been added chapters on normal blood pressure, pulse pressure, venous and capillary blood pressure, blood pressure in children, nephritis, cardiac disease, and the therapeutic value of drugs affecting blood pressure.

Octavo of 480 pages, illustrated. By FRANCIS A. FAUGHT, M.D., formerly Instructor in Medicine at the Medico-Chirurgical College of Philadelphia. Cloth, 15s. net.

Strouse & Perry's Food for the Sick

JUST READY

This manual translates the terms of the laboratory into the terms of the kitchen. It contains 232 diets and menus and 125 special recipes. Diets are given for diabetes *(starvation treatment)*, gout, nephritis, high blood pressure, kidney stone, diseases of the stomach, intestines, liver, gall-stones, tuberculosis, fevers, skin affections, obesity, anæmia, &c.

12mo of 270 pages. By SOLOMON STROUSE, M.D., Professor of Medicine, Post-Graduate Medical School, Chicago; and MAUDE A. PERRY, B.S., Dietitian at Michael Reese Hospital. Cloth, 6s. 6d. net.

Abt's The Baby's Food

JUST READY

This practical guide gives minute directions for the preparation of food for the baby. You get diets for constipation, care of nipples and bottles, &c., and recipes for beverages of all kinds, milk preparations, soups and broths, puddings and cereal preparations, custards, eggs, vegetables, fruits, meats, sea foods, and breads. Decidedly a good book for your mother patients.

12mo of 143 pages. By ISAAC A. ABT, Professor of Diseases of Children, Northwestern University Medical School. Cloth, 5s. net.

Radasch's Anatomy

JUST ISSUED

Dr. Radasch has written an anatomy along *new* lines. For instance, the external anatomy is continued from one segment to another without interruption. The various pathways are so arranged that impulses may be traced in an uninterrupted manner from origin to termination. The *nomenclature* adopted eliminates the confusion usually arising between comparative anatomy and embryology.

Octavo of 489 pages, illustrated. By HENRY E. RADASCH, M.D., Assistant Professor of Histology and Embryology, Jefferson Medical College. Cloth, 15s. net.

Books sent, Carriage Paid, on Receipt of Price.

OPERATIVE TREATMENT OF FRACTURES.

By Sir ARBUTHNOT LANE, Bart., M.S.

SECOND EDITION. With 226 Illustrations. 10s.

THE MEDICAL PUBLISHING COMPANY, LTD., 23, BARTHOLOMEW CLOSE, E.C.

Thirty-fifth Year. **NOW READY.** *Fully illustrated in Colours, and Black and White.* **10/- net**

THE

MEDICAL ANNUAL, 1917

BY TWENTY-SEVEN DISTINGUISHED CONTRIBUTORS.

This year's Volume has a unique value, for while the civil side of the Practitioner's work has received every attention as before, it also provides a careful review of the latest achievements in War Surgery and Medicine which cannot be obtained from any other single source. This will be of value to every Practitioner in dealing with such cases, with which he will inevitably be confronted now and in the years to come.

Thus the new "Annual" continues to be a digest of the best modern teaching, culled by experts from the medical literature of the world.

"THE HOUSE FOR EVERYTHING ELECTRO-MEDICAL."

THE "GALVANOSET" No. 1.

The Latest Development in MEDICAL ELECTRICITY.

SEND FOR DESCRIPTIVE PAMPHLET.

For any Continuous Current supply of any voltage ... ... Price £3 8 0
Extra for Faradisation Attachment ... ... ,, £1 15 0

Owing to prevailing conditions our prices are subject to fluctuation.

For TRUE GALVANISATION, TRUE FARADISATION, IONISATION, UNDULATING CURRENTS, ELECTROLYSIS, MUSCLE REACTION TESTING, ILLUMINATION OF SURGICAL LAMPS.

The "GALVANOSET" is a device for safely utilising the main supply of electricity for medical purposes.

The following advantages render the "GALVANOSET" superior to all other methods:—

Nothing to get out of order. Nothing to wear out. Any desired current.
No expense for upkeep. Costs less than one farthing per hour to run. Light and portable.
Always ready for use. Safe under all circumstances. Provides a true galvanic current.
Does not require re-charging. Finest range of adjustment. Weighs 7 lbs. only.

The Commandant of the Red Cross Auxiliary Hospital for Officers, 11, Chichester-terrace, Brighton writes:—"I shall be obliged if you will send me by return another Galvanoset. The two I have already are working excellently. You will remember that the current is 220 continuous."

Demonstrations Daily on Ionisation, Galvanisation, Faradisation, Electrolysis, &c., 3 to 6 p.m.

THE
SIMPLEX "606" INFUSION SET
(PAT. APP. FOR.)

A ONE MAN "606" APPARATUS.

ADVANTAGES CLAIMED OVER GRAVITY METHOD.

A.—Everything is at your hand, and the whole management of the instrument is entirely under the operator's control.
B.—There is absence of noise and confusion which may occur if an assistant (in the gravity method) becomes tired from the monotony of jumping up and down to pour in the liquids.
C.—Less water is given to a patient, which is not only speedier but economical.
D.—It is easily portable and can be carried anywhere.
E.—No dust can get into the tubes.
F.—One or six doses can be given without any more trouble than having to put the tourniquet on when a patient lies down, that is to say, after the previous one has got up.
G.—As no assistant is absolutely necessary, it is a great saving in labour, which means less expense and confusion.
H.—ONE operation can be performed in 30 to 35 seconds if the bore of the needle is not too small.
I.—By following the water in the glass you know at once whether or no the operation will be successful: for if the water moves slowly or does not move the vein is not entered properly.
J.—The appearance of the gravity method, for the first time, is one that gives a patient a sinking sensation.

ADVANTAGE OVER THE SYRINGE.

A.—As no blood should pass back through the needle, one sterilization is enough for a hundred or more patients.
B.—It is safer, and in a large batch of patients it is quicker and less exacting to the operator.
C.—Syringes are easily broken, and if one part is smashed it cannot be replaced, for another entirely new syringe has to be bought.

A conclusion based on trials in Hospital and in Private Practice of

'Wander' Malt Extract with Paraffin.

(50% Pure Liquid Paraffin.)

During the last year a large number of trials of this interesting product have been made. Many practitioners have kindly furnished us with reports as to the results. One definite conclusion arrived at by a study of these reports is that the product possesses distinct advantages in the treatment of **Constipation in Children and Infants.**

The almost general unanimity of opinion as to its success in this field of use is ascribed to the following features:

1. Extreme palatability—young patients take it with avidity.
2. Though containing 50% by weight of Pure Liquid Paraffin, it is not oily in nature, being presented in a dry, crystalline powder form.
3. Ease and variety of methods of administration. It mixes instantly with water or milk and does not separate—can also be given on bread and butter or dry from a spoon.
4. The oil being in an extremely fine state of globular division mixes rapidly and completely with the intestinal contents, thus not only lubricating the fæcal mass, but preventing the formation of scybala, and ensuring soft, homogeneous stools.
5. The nutrient, digestive and slightly laxative qualities of the "Wander" Malt Extract being retained unimpaired add to the value of the product and make it an ideal medium in a large number of cases where dyspeptic and badly-nourished conditions are also present.
6. That in the case of Infants' Constipation it can be administered in half to one teaspoonful doses, mixed with a little water, or milk, after feeding, or in the case of the artificially fed, mixed with the contents of the bottle. Its addition to cow's milk also prevents the formation of indigestible curds, and supplies the deficiency of carbohydrate. For these purposes the preparation is stated to be ideal.

The product has been used with advantage in many conditions where Paraffin is indicated, viz.: in **Hæmorrhoids, Stasis, After Intestinal Operations, Typhoid Convalescence, Mucous Colitis, Thread-Worm Infection and Intestinal Toxæmia.**

℞ "*Wander*" *Ext. Malti c. Paraffin.*

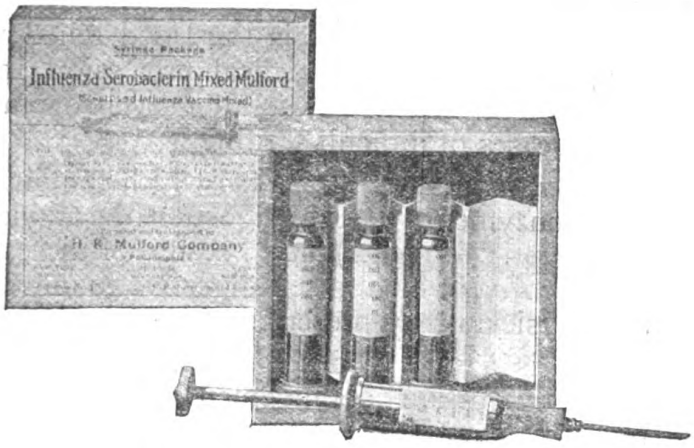
Academy of Medicine, Paris, 10th Nov., 1908.
Academy of Sciences, Paris, 14th Dec., 1908.

URIC ACID is never found free in the organism. It always exists in a state of combination with Soda, Ammonia, &c.; it forms biurates or quadriurates, which are complex and not easily soluble.

URODONAL by reason of its special composition, is able to effect the double chemical decompositions which liberate the Uric Acid from the combinations where it is fixed, and cause it to be easily eliminated in the urine.

URODONAL is a most powerful solvent of **URIC ACID,** because it can destroy its organic combinations.



URODONAL.—Price 5/- and 12/- per bottle.

Prescribed by the Medical Profession for 35 years.

The MEDICAL PRESS & CIRCULAR (London, Eng.) says:
"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in his treatment of the sick."

"AN OUTSTANDING FOOD."

Everywhere Benger's is the Food relied upon by the British medical profession, in the prostration of illness, after severe operations, and in cases of difficult feeding.

Benger's is the One Food which contains the active enzymes of natural digestion (the amylolytic and tryptic ferments), and because of these, *it is the One Food* which is self-digestive to any extent the physician may prescribe.

It is a safe food to give in sickness and in severe digestive derangement, and is usually retained when all other foods are rejected.

BENGER'S FOOD (which is to be prepared with fresh new milk) is enjoyed by invalids who are unable to assimilate milk alone or milk and water.

BENGER'S
Food

for INFANTS, INVALIDS, AND THE AGED,

is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

COLLOSOL FERROMALT

Pure Malt Extract with Colloidal Iron.

CROOKES'

COLLOSOLS are Drugs in the COLLOID STATE.

COLLOSOLS are isotonic and isomorphic with the elements of the body.

The iron in this preparation is in an extremely fine state of subdivision, and is present to the extent of 0·1%. When administering iron it should be remembered that the total iron content of the normal body does not exceed 37 grains, and although organic compounds of iron have been recommended, the inorganic iron is held by many to be the most efficient in the only true test of the value of an iron preparation—*i.e.*, increase of hæmoglobin. **COLLOSOL FERROMALT** should be taken after meals. Diffusion rapidly takes place over the whole of the stomach, and the known low chemical affinity of colloids prevents too rapid absorption of iron in individual positions, and the amino-acids formed during the process of digestion are enabled to absorb into their complex molecule a proportion of iron essential for the synthesis of hæmoglobin. **COLLOSOL FERROMALT** does not cause constipation or digestive troubles.

COLLOSOL IODINE

COLLOSOL IODINE is prepared in aqueous solution, as an Oil, an Ointment, and as a Pasta.

The following extract from an article by one of the foremost dermatologists, in the *British Medical Journal* of May 12th, 1917, testifies to the efficacy of **COLLOSOL IODINE OIL** in the treatment of

CHILBLAINS.

"In a severe case of chilblains in the first stage, that of a woman of 37, whose fingers were so swollen that they looked like sausages, under the application of Collosol Iodine Oil rubbed in four or five times a day every trace of the condition disappeared in four days."

COLLOSOLS are prepared for the Proprietors, Crookes' Collosols Ltd., at

THE CROOKES' LABORATORIES,

50, Elgin Crescent, LONDON, W. 11.

SUBITOL

(The product of an Allied Country)

HAS USEFULLY and EFFICIENTLY REPLACED

ICHTHYOL

THE attention of surgeons is directed to the excellent results which have been obtained in the treatment of septic wounds with Ichthyol and glycerine. Dressings do not need changing so frequently, and thus not only is the disturbance to the patient lessened, but valuable time is saved. Even the most septic wounds have been found to respond readily to the above treatment.

Ichthyol being an enemy product

SUBITOL

has been substituted, and has already been found to give equally good results.

The therapeutic efficiency and usefulness of Ichthyol in the treatment of Gastro-Intestinal Affections, Vesical Catarrh, Endometritis, Eczema, Erythema, Hæmorrhoids, Acute and Chronic Arthritis is sustained when **SUBITOL** is prescribed instead of Ichthyol.

SAMPLE AND PAMPHLET SENT FREE.

Prices: 4 ozs., 2/-; 8 ozs., 3/6; 1 lb., 5/6; also in larger containers for Hospital use.

BRITISH FIRM.

'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid, containing all the soluble constituents of the gastric juice, preserved in an agreeable aromatic menstruum. It represents both the peptic and milk curdling ferments obtained directly from the fresh peptic glands.

PEPSENCIA is acceptable to the most delicate and fastidious patient, while it excels all other allied preparations in activity and utility.

One teaspoonful before or after a meal will be found of service in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz., 8 oz. and 16 oz. bottles at 2/4, 4/2 and 7/8 each, and Winchester Quarts at 33/- each.

Peptogenic Milk Powder

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 2/4 and 4/8 each.

Specimens and literature will be forwarded on request.

Originated and Manufactured by

Fairchild Bros. & Foster,

Advances in Treatment

CONSTIPATION

"Byno Chrismol"

(TRADE MARKS)

marks a new departure in the treatment of Chronic Constipation, etc. It presents 50 per cent. by volume of "Chrismol," a specially selected and purified Russian mineral oil in intimate combination with the "Allenburys" Malt Extract.

"Byno Chrismol" possesses the following advantages:

It is prepared with mineral oil of the proper viscosity and chemical constitution to ensure efficient lubrication with a complete absence of bye-effects.

The intimate combination of the mineral oil and "Allenburys" Malt Extract without an emulsifying agent, ensures the maximum activity of the oil as a lubricating agent, and removes the inconvenience that sometimes follows insufficient admixture of the lubricant with the intestinal contents.

It possesses no oily taste. The "Allenburys" Malt Extract present assists digestion and assimilation.

"Byno Chrismol" is specially indicated in Chronic Constipation with symptoms of auto-intoxication, Intestinal Stasis, Mucous Colitis and in the convalescent stage of Typhoid Fever; also after Child-birth, during the nursing period and whenever a simple laxative is required by child or adult.

DOSE: A dessert-spoonful, or more, two or three times a day.

In bottles at 2/6 and 4/6 each. **Sample free on request.**

'Bynogen'

Trade Mark

Brings Health

The Improved Casein-Glycerophosphate Food

Recommended in all Enfeebled Conditions, Mental and Nervous Exhaustion, Insomnia, Convalescence after Illness, etc.

"Bynogen" is a highly concentrated food of acknowledged value. It is specially rich in phosphorus, which is present in the condition in which it is found in brain substance and other nervous tissues.

Formula :

Pure, Soluble Milk Protein - 75 per cent. Sodium Glycerophosphate 2 per cent.
Dextrin-Maltose (specially prepared) 20 ,, Calcium Glycerophosphate 2 ,,
Magnesium Glycerophosphate 1 per cent.

Advantages :

Physical.

Possesses a most attractive flavour and aroma, mixes readily with milk, water, and other fluids. May be eaten dry, if desired, or sprinkled on articles of solid food. Keeps good indefinitely.

Therapeutic.

The percentage of Nitrogen is high. The Carbohydrate is in the most easily assimilable form. The mixed Glycerophosphates present the inorganic bases common in food-stuffs and do not cause constipation.

Medical Men are invited to write for samples of this unique Nutrient and Nerve Restorative.

Obtainable from all Pharmacists, in bottles with cartons at 1/9 and 3/- each.

Figure of a Hindu-Burmese legendary King, Bawdithada, armed with a sword and carrying a human head. From very ancient times this King was to the Burmese the great prototype of invulnerability. By having his figure tatooed in red above the waist, a warrior became proof against enemy weapons. The dye was mixed with human fat and with "water of the 5000 years of the religion." While he was being tatooed the aspirant held a piece of human flesh between his teeth and muttered the incantation inscribed round the figure: "I, Bawdithada, who am qualifying to be the great robber chief Angulimalla, am now going fast ahead." Belief in magic is still strong among the Burmese and during the disturbances which followed the annexation of Upper Burma by the British in 1886, incantations and amulets played a great part in keeping the revolutionaries together. Date, Legendary.

COPYRIGHT

"MALTINE"

'Maltine" presents the proteids, carbohydrates, and organic phosphates of malt in an agreeable, convenient, and readily assimilable form. It is standardised in diastase, concentrated, and semi-liquid, and perfectly soluble.

Special Indication:—

In Infant Feeding, to humanise cow's milk and prevent constipation.

Full particulars, together with complete Feeding Tables, giving the proportions of milk and water for different ages and periods of feeding, as also samples of "MALTINE," may be obtained free of charge by Medical Men on application to the Company.

"MALTINE" WITH IRON.

Each Fluid Ounce contains—IRON PYROPHOSPHATE ... 8 grains.

This is a particularly bland and assimilable preparation of Iron, in which e astringency of the ferruginous salt is counteracted by the slightly laxative action the "MALTINE" base.

'MALTINE" WITH COD LIVER OIL

a complete, physiologically proportioned food, containing all the elements of nutrition easily assimilated form, possesses valuable diastasic power, and is distinguished by Palatability. *The British Medical Journal* states: "Apart from its own dietetic ue, 'Maltine,' when combined with Cod Liver Oil, certainly enables the latter to taken by persons who can neither swallow nor assimilate it in any other form."

The word "MALTINE" is our Trade Mark.

In prescribing kindly specify "MALTINE COMPANY."

The great Mongol Emperor, Kublai Khan, made a claim for submission upon the ancient kingdom of Burma. He overran the country as far as the Irrawaddy delta: "and then the battle began to rage furiously with sword and mace. The king's troops were far more in numbers than the Tartars, but they were not of such metal, nor so inured to war, otherwise the Tartars who were so few in number could never have stood against them. Great was the medley, and dire and perilous was the fight that was fought on both sides; but the Tartars had the best of it." However, the particular Burmese warrior of high rank here depicted in the act of decapitating his adversary, had the better of the Tartar. Date, A.D. 1284.

Timely 'TABLOID' Products

TRADE MARK 'TABLOID' BRAND

'Epinine' Compound
(Trade Mark)

For Throat and Voice

contains 'Epinine,' the synthetic hæmostatic. Soothes the sensitive membranes and braces the larynx.

Supplied in bottles of 25 at 8d. and 100 at 2/0 per bottle

B.P. OR BETTER

TRADE MARK 'TABLOID' BRAND

Quinine Compound

A Useful Antipyretic

presenting cinchona alkaloids, antifebrin, camphor, Ipecacuanha and cascara sagrada. Acceptable and effective.

Supplied in bottles of 25 at 1/0 and 100 at 3/0 per bottle

TRADE MARK 'TABLOID' BRAND **Aspirin**

The Perfection of Therapeutic Efficiency

Each product contains the stated weight of pure medicament. Absolutely free from talc and boric acid.

Supplied as follow:
gr. 5, in bottles of 25 at 1/4, and 100, at 4/0 per bottle;
0·5 gm., in bottles of 25 at 2/0, and 100, at 6/0 per bottle

The desire on the part of an ancient Burmese King to possess a white elephant provided, at least once, a casus belli between Burma and Siam. This animal being in the popular estimation the distinctive mark of a Buddhist sovereign in Indo-China, Bureng Naung, in spite of great power and glory, was not happy without one. "It is reported that if this King knew any other King that had any of these white Eliphantes and would not send them unto him, that he would hazarde his whole kingdom to conquer him; he esteemeth these white Eliphantes verie deerely and they are had in great regarde, and kept with verie meete service, everie one of them in a house, all gilded over, and they have their meate given them in vessells of silver and gold." The Burmese victor here depicted on the point of seizing an adversary, gives an idea of the appearance of one of the warriors—of royal rank—who helped in the great war to secure three of the four white elephants in the possession of the King of Siam. Date, A.D. 1562.

TRADE MARK 'TABLOID' BRAND

Ammoniated Quinine with Cinnamon *(Capsules)*

Acceptable to all

An ideal means of administering this combination. The nauseating taste of fluid preparations is entirely absent.

Supplied in boxes of 20 at 1/4 per box

HORMOTONE

The Dynamogenic Hormone Tonic for the Fatigue Syndrome and all ASTHENIC CONDITIONS.

Low blood pressure is one of the cardinal symptoms of a hypoadrenia, and **HORMOTONE** is essentially formulated to meet this condition. Functional hypoadrenia according to Sajous, is the symptom-complex of deficient activity of the adrenals, due to inadequate development, exhaustion by fatigue, senile degeneration, or any other factor which, without provoking organic lesions in the organs or their nerve paths, is capable of reducing their secretory activity. Asthenia, sensitiveness to cold and cold extremities, weak cardiac action and pulse, anorexia, anemia, slow metabolism, constipation, and psychasthenia are the main symptoms of this condition. **HORMOTONE** has proved very efficacious in overcoming these symptoms.

A well-known Physician writes:—

"No medicine of this character has ever before been devised that produces the uniformly good results when used in suitable cases as does **Hormotone,** and it has come to be my main reliance in a certain class of neurasthenics with a loss of tone in the general musculature."

Dose: One or two tablets three times daily before meals.

In neurasthenia associated with high blood pressure use HORMOTONE WITHOUT PITUITARY

The FitzPatrick Lectures
ON
MEDICINE, MAGIC, AND RELIGION.

Delivered before the Royal College of Physicians of London,

BY W. H. R. RIVERS, M.D. LOND., F.R.C.P. LOND., F.R.S.,
FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE.

LECTURE I.

MR. PRESIDENT AND FELLOWS,—In the lectures under the FitzPatrick foundation delivered before the College last year[1] I dealt with the relations between medicine, magic, and religion descriptively and from the sociological and psychological points of view. I showed that in Melanesia and New Guinea, which I chose as the region to illustrate my subject, there is an intimate connexion between three sets of social process which are clearly distinguished from one another by ourselves and other civilised peoples. I dealt briefly with some of the psychological factors underlying the union between the three kinds of process, but left altogether on one side any consideration of the mechanisms by which the relations between medicine, magic, and religion had come into being, and those by which processes so closely related in one part of the world had elsewhere become distinct and self-contained departments of social life. I have chosen this historical and evolutionary treatment for the task with which you have again honoured me.

EVOLUTION OF SOCIAL CUSTOMS AND INSTITUTIONS.

I must begin by considering briefly the general problem concerning the nature of the evolutionary process in its relation to the history of human society. The practice of medicine is a social process, subject to the same laws and to be studied by the same methods as other social processes. The chief aim of these lectures is by means of the relations between medicine, magic, and religion to illustrate the principles and methods which should guide and direct the study of the history of social institutions.

Independent Evolution.

If I had been giving these lectures only a few years ago ny mode of treatment would have been very simple. At hat time, in common with most students of human society, believed that after a dispersal widely over the earth, vhich had taken place at an epoch so distant as to place its tudy almost without the range of practical science, mankind ad evolved his customs and institutions with a high, even n some cases a complete, degree of independence. When found close similarity of custom or belief in widely eparated places I was content to ascribe it to a process of ndependent evolution, the course of which had been deter*ined* by the tendency of the human mind to respond in ertain uniform ways to the action of its physical and social nvironment. I should have been content with the position *at the* close relation of medicine to magic and religion, hich I endeavoured last year to demonstrate for Melanesia and ew Guinea, represents only one stage in a process of differtiation whereby one kind of social activity has developed sewhere into three distinct departments of social life. I ould have held that Melanesia and New Guinea have eserved for us a stage in the evolution of human society in nich this differentiation has made so little progress that it still difficult to distinguish medicine from magic and igion, while among ourselves the process of differentiation s gone so far that each of the two departments which our n society has preserved has its own specialised practiners, its own code of social regulations, and its own ly of beliefs concerning the relation of mankind to his roundings.

Moreover, when comparing the pathological ideas and the gnostic and therapeutic practices of different peoples, I uld have held any similarities which became apparent e the natural result of the unity of action of the human nd. The diseases of one part of the world are so much those of another that I should have regarded it as the st natural thing in the world that mankind should have lved similar beliefs concerning the nature of disease and similar practices by which to modify or neutralise its effects.

I should have explained the similarities between the beliefs and practices of medicine and those of magic and religion in a similar manner. I should have argued that, whether magic and religion have grown out of the beliefs and sentiments of mankind towards the mysteries of Nature or towards those of his own birth, life and death, or towards both together, these mysteries are everywhere similar in character. I should have regarded it as natural that the mind of man in its making should have reacted towards them in ways so similar as to have produced the worship of the sun and other heavenly bodies, of vegetation and of other natural forces, together with the cults of the dead which are found in so many parts of the earth. It would not have surprised me that a body of customs and beliefs embodying the reaction of mankind towards the appearances of nature or of his own life should be closely connected with those embodying his attitude towards disease. If then, as now, I had given a pre-eminent degree of importance to the great mystery of death as the most important motive in the development of the religion of mankind, the connexion of religion with the art designed to meet disease, the harbinger of death, would have seemed especially natural. I should have dwelt on the vast part which ideas connected with death and the life after death have taken in the religious development of mankind, and should have regarded the close connexion between medicine and religion as the natural consequence of the intimate relation between disease and death.

In this brief sketch of what I should have said if I had been giving the lectures a few years ago, there is much which I still believe to be true. That running through the history of mankind there has been in action a process of specialisation of social function stands beyond all doubt, and I should have been keeping strictly within the truth in regarding the increasing distinction of medicine from magic and religion as an example of this process of specialisation. There would also have been much truth in the supposition that disease and death are so closely connected that, even if the earth had been divided up into independent and self-contained departments, we should have expected much similarity in the reaction of different groups of mankind towards them. The fault I now find with the account I have just given is not so much that it is false, but that it is far from being the whole truth. It errs by giving a far too simple account of a process which has in reality been exceedingly complex.

Transmission as a Factor in Human Culture.

The great change which has taken place in our ideas concerning the value of such a scheme of evolution as I have sketched is due to several causes. I have time to-day only to mention one. This is that until recently far too little attention has been paid to the influences of degeneration in the history of human society. At one time the savage and barbarous cultures of mankind were universally regarded as examples of degeneration, but with the general acceptance of the doctrine of evolution degeneration was forgotten or neglected. In accordance with the general course of the progress of knowledge an idea which had till then been dominant was thrust aside, and even the many cases where degeneration in human society is obvious were ignored or held to be of little account. As one among many examples of this neglect I may mention that students were led to attach great importance to the rude means of navigation now found on many parts of the earth. The possibility that this rude condition may have been the result of degeneration was neglected. It was concluded that voyages on the sea had taken no appreciable part in the early wanderings of mankind. Since, in the absence of communication by sea, the existing connexions between the different continents are insufficient to explain the present distribution of mankind, ancient land connexions were assumed, thus putting back the dispersal of mankind to so remote a date as to leave ample scope for processes of independent development. It is only necessary to show that the art of navigation might not only degenerate but even disappear,[2] and voyages by sea again enter into our schemes of the early peopling of the earth, thus bringing transmission out of the lumber-room into which it had been cast by most students of human society.

[1] THE LANCET, 1916, i., 59, 117.

[2] W. H. R. Rivers: The Disappearance of Useful Arts. Festschrifft. Edvard Westermarck, Helsingfors, 1912, p. 109.

Once we acknowledge transmission as an important factor in the history of human culture, once we appreciate the important part taken by degeneration in this history, and many old problems can be seen in quite a new light. When we find a mode of treating disease closely related to a magical or religious practice, it becomes possible that the relation does not represent a stage in a process whereby medicine is gradually being differentiated from magic or religion, but the process may be rather one of assimilation. A therapeutic practice, devoid of any magical or religious character in its original home, may acquire this character when introduced elsewhere. The magical or religious guise thus obtained by a therapeutic practice would in such a case be due to the prominence of magic or religion in the culture of the people among whom the practice has been introduced. On the other hand, a magical or religious practice may have aspects which to a people who possess a genuine art of medicine suggest therapeutic or hygenic applications. These may lead to its becoming part of the medical art of its new home and to the complete disappearance of its magical or religious character. In each case the relation of medicine with magic or religion is due to a process of assimilation whereby an introduced practice has been endowed by the people who have adopted it with the features characteristic of their own culture.

Instead of human culture presenting us with a simple process of direct evolution we have a highly complex process of interaction between peoples and their cultures, producing blended products, in the case before us blends of medicine with magic and religion, which need new methods of inquiry and long years of patient study before the exact nature of the process, the whole instead of the partial truth, can be attained.

RELATIONS OF MEDICINE, MAGIC, AND RELIGION IN VARIOUS PARTS.

In my lectures last year I dealt with a limited area, with Melanesia and New Guinea, and even then I attempted no full survey, but was content to pick out a few salient examples to illustrate the relations of medicine with magic or religion. Before I enter on the special task of these lectures I must briefly sketch the nature of the relations between medicine, magic, and religion in other parts of the world. In this survey I shall begin with the countries adjacent to Melanesia.

Australia.

Australia is characterised by the large part taken by human agency in the beliefs concerning the production of disease. According to the prevailing views, this continent is held to be the special home of magic, and there is no doubt that the Australian attitude towards disease is closely bound up with practices resembling those to which the name of magic is usually given.

It is noteworthy, however, that the form of magic most widely spread over the earth, that known as sympathetic, rarely occurs in Australia. It is exceptional in this continent to act upon some part of a person with the idea of inflicting disease upon him. The usual process by which an Australian sorcerer inflicts disease is to point at his victim a bone from a dead person. It is believed that he is able to project some morbific influence into his victim, the process resembling one of which I gave an example from the Banks Islands last year.[3]

The use of part of a dead man in this process raises the question whether the method of the Australian sorcerer comes as definitely within the sphere of magic as is usually supposed. It is possible that this and other of his methods do not depend altogether, perhaps not at all, on a belief in non-human agency. The Australians certainly believe in the production of disease through the action of spiritual beings, such as the ghosts of the dead, and especially the ghosts of certain beings to whom tradition assigns the ancestry of the social group or the introduction of new elements of culture. Australia thus presents examples of both the chief categories of causation which are found in Melanesia, but it is a question whether the cases which on superficial observation seem clearly to belong to the category of magic may not be only the degenerate products of a former belief in the production of disease by spiritual beings, and especially by the ghosts of the dead.

In any case, the immediate agent to whom the Australians usually ascribe the occurrence of disease is a human being, and in accordance with this belief the object of the friends of a person who becomes ill is to discover and propitiate the man to whose action the disease is ascribed. The process of diagnosis is mainly or exclusively directed to discover the human agent, and the only treatment is to convince the patient that his spell has been removed. Whether disease is ascribed to human or spiritual agency, the therapeutic practice is usually based on the belief that the agent has implanted in the body of his victim some material object—a piece of bone, a crystal, or a pebble—as the vehicle of the disease. It is by the supposed extraction of such an object that the cure is effected, suction being the most frequent process by which the object is removed.

Polynesia.

While Australia lying on one side of Melanesia provides, at any rate from certain points of view, an example of the relation between medicine and magic, Polynesia lying upon the other side shows us a striking example of the intimate relation between medicine and religion. In some parts of Polynesia magic appears to be absent and with the exception of a few simple remedies, the cure of disease is sought by means of direct appeal to higher powers, and especially to those beings called *atua*, who are almost certainly derived from the ghosts of dead ancestors.

In this part of the world especial importance is attached to the process of prognosis which is carried out by men who enter into conditions of trance, in which they are believed to be possessed by the ghosts of the dead. In this condition the possessed person answers inquiries concerning the outcome of the illness and the friends of the patient are content to accept the fiat thus issued and do not seek to interfere with the result by the employment of any therapeutic measures. Among some peoples of Polynesia medicine can hardly be said to exist, so exclusively do the people reply upon divine help in their attitude towards disease. Even where definite therapeutic remedies are employed there is often evidence that these are of recent introduction. Thus, Mariner states[4] that the Tongans looked to the gods for relief from disease, using for this purpose rites of invocation and sacrifice. They had learnt from the Fijians not long before Mariner's stay in the islands the surgical procedures which form almost the only measures which can be regarded as strictly therapeutic.

In some parts of Polynesia the abstraction of blood, usually by means of incisions and scarifications, is a favourite remedy. Vapour and cold baths and massage are also employed as therapeutic measures, but little use is made of herbs or other internal remedies in most parts of Polynesia. An extensive vegetable pharmacopœia has been recorded from New Zealand, but, according to Elsdon Best,[5] the greatest living authority on the Maories, this is a recent growth. Before the coming of European influence the Maories were content to rely mainly upon spiritual agencies similar to those invoked by the inhabitants of other parts of Polynesia. Such internal remedies as were used in Tonga had been derived from Fiji.[6]

The medical practice of the Hawaiian Islands, though intimately connected with religion, contains more elements of a medical character. David Malo,[7] a native authority, says that the medical treatment of the sick was a matter that belonged to the worship of the gods. The treatment was applied by a *kahuna* or priest, but it included the administration of a number of herbs as well as the use of the vapour bath. The religious character of the treatment is shown, however, by offerings to the gods at different stages, and when the patient was a chief no medicine was ever administered without prayer.

In parts of Polynesia there is a belief in the production of disease by human agency and by the employment of procedures resembling the magic of other places, but beliefs of this kind are of little account beside the religious attitude. In some islands they appear to be completely absent, one island where this is certainly the case being the small Polynesian settlement of Tikopia, which lies upon the fringe of Melanesia.[8]

Indonesia.

The Malay Archipelago, now usually known as Indonesia, is of especial interest in relation to Melanesia, Polynesia, and Australia, because it is almost certain that the chief external influences which have reached these areas came by way of this archipelago. Indonesia is the seat of much recent contact with the Chinese, while before this many parts of it were saturated with Hindu influence. Probably as the result of the many influences to which it has been exposed the medical art of Indonesia presents more variety than that of either Melanesia or Polynesia. The occurrence of disease is ascribed to human agency as well as to the activity of evil spirits, of the ghosts of ancestors and relatives, and of beings who can definitely be regarded as gods.

One of the modes in which purely human agency is believed to produce disease is by acting upon separated parts of the body the so-called sympathetic magic, and though the evidence is not conclusive it would appear that this form of magic rests upon the belief in a divisible soul-substance similar to that held by the Kai of New Guinea.[9] In Melanesia and Australia it is sometimes difficult to be sure whether the injurious effects which follow the rites of a sorcerer do not depend upon the administration of poisons. In Indonesia this use of poisons stands beyond doubt, the most striking example being the production of a lingering intestinal complaint, often ending fatally, by the administration of powdered bamboo. Even when the morbid effects can confidently be ascribed to a poison, however, the utterance of incantations and other actions of the poisoner show that the process is not far removed from magic, and the agent himself probably fails to distinguish between measures in which he administers actual poisons and those in which the morbid effects are entirely due to the belief of the victim in the magical powers of one whom he has offended.

The belief in the production of disease by magic, however, plays a relatively small rôle in Indonesia compared with that in which disease is ascribed to the action of spiritual or divine beings. One of the most frequent beliefs is that, also widely prevalent in Melanesia, in which disease is ascribed to the abstraction of the soul or soul-substance. It is believed that the soul is sometimes devoured by the spirits who steal it, in which case a fatal issue is inevitable. In other cases the soul can be recovered by a priest, and the nature of the rites performed for this purpose shows clearly that the beliefs of this kind come definitely into the category of religion.

An important feature of the rites performed by a priest when dealing with disease in the island of Nias[10] is that he makes images of wood called *adu*, which probably represent ancestral ghosts. Many different kinds of *adu*, bearing special names, are made for different kinds of illness. Thus, one kind is made when the patient is suffering from fever, with swollen feet and a sensation of heaviness in the limbs, another when fever is accompanied by nightmares, and a third when there are also pains in head and body. The *adu* are made in different forms, an important feature being that the more serious the illness the larger is the number of kinds of wood which must be used. In a bad case, the *adu ba nbumbu*, made when all other remedies have failed, from 50 to 100 images are made of as many kinds of wood as can be obtained.

[9] THE LANCET, 1916, i., 63.

[10] J. P. K. de Zwaan: Die Heilkunde der Niasser, Haag, 1913, p. 1 et seq.

An *adu* is treated in various ways. It may be hung on a tree as an offering to the evil spirit who is believed to be producing the disease, or it may be set up before the patient or before or on the roof of his house. It may be thrown into a river, the belief in this case being that the disease has entered the *adu* and is carried away by the stream. The disease may also be transferred from the patient by touching him with a young pig which is then slaughtered and its blood smeared on the *adu*.

Various rites accompany the use of the *adu*. Offerings may be made to the beings to whom the action of the disease is ascribed, and in the case of the *adu ba mbumbu* the priest climbs on the roof of the patient's house to pray to the "sun-god." The patient may be isolated and his diet regulated, and he may be given remedies, such as fungi from the tree believed to be inhabited by the evil spirit to which the disease is ascribed.

In some cases the occurrence of disease is believed to affect a person because he or his relatives have committed an offence against the beings to whom the disease is ascribed, but so far as our information goes it appears that more often disease is believed to come about through the will of spirit or god independently of any sin on the part of the patient.

In addition to the measures which depend upon appeal to non-human and divine beings, remedies of the domestic order are frequently employed. This branch of medicine seems to have reached a higher degree of development than in Oceania, for these remedies are used by special practitioners, often women, called *dukun* in the island of Nias, who use massage and various internal remedies. Though definite information is lacking it is probable that the letting of blood by means of scarification and cupping is also the business of these practitioners.

I have dealt at some length with the medicine of Australia, Polynesia, and Indonesia because the culture of these three areas stands in a special relation to that of Melanesia. With few exceptions the people of Melanesia, Polynesia, and Indonesia, regions sometimes known collectively as Austronesia, speak languages which belong to closely related families, and have many other practices in common. We should therefore expect to find the similarity in their medical arts and in the relation of these to magic and religion which we have seen actually to exist. I must deal with the medicine of other parts of the world more briefly.

India.

Corresponding with its advanced civilisation, we find in India an extensive pharmacopœia and a surgery from which that of Europe has taken more than one lesson. The practice of rhinoplasty was borrowed from India, while the first performance of surgical operations under hypnotism was largely due to the experience of this practice gained by Esdaile in this country.

Even this relatively advanced art, however, seems to have greatly degenerated from that which belonged to Indian medicine about the fifth century A.D., the degeneration apparently being due to the gradual preponderance of an old indigenous art over one introduced and developed by an immigrant people. Even at its best times, however, the close relation of medicine with religion was shown by the special practice of the medical art by members of the priestly brahmanic caste. At the present time the frequent use of formulas when remedies are administered shows clearly how close is the alliance between medicine and religion, even among the more highly civilised sections of the Indian population.

Among the less advanced sections of the community the connexion between medicine and religion is still more definite. The folk-medicine of India at the present time is chiefly based on the belief that disease depends upon possession by a spirit, and the historians of Indian medicine speak of possession as characteristic of its earliest stage.

When disease is ascribed to possession the rational remedy is to rid the patient of that by which he is possessed, and, as we should expect, rites of exorcism are very prominent in Indian medicine and religion.

In India we also meet the idea of disease as a punishment for sin, the beings who thus inflict disease when offended including both the ghosts of ancestors and gods.

Not only is disease believed to fall upon man as a punishment for offences which he has committed in his present life, but the doctrine of transmigration has brought with it the belief that disease may occur as a punishment for offences committed in a former existence, and that they are to be remedied by the performance of religious observances.

One people of India, the Todas, whose culture is in many ways peculiar, exhibit an interesting phase in the specialisation of medicine and religion. There is a definite distinction between the priest and the doctor, together with a close similarity in the formulas of the therapeutic measures of the one and the divinatory and religious rites of the other.[11]

China and Japan.

China presents us with an example of medicine which resembles in many respects that of our own Middle Ages. The main doctrine upon which Chinese medicine rests is that disease depends on disturbance of the normal equilibrium between the blood, the humours, and the life-spirit. The chief element in the system of diagnosis is a highly elaborate examination of the pulse.

In the therapeutic side there is a very extensive pharmacopœia, one writer alone enumerating no less than 1892 remedies. Animal substances are frequently used, while the moxa, acupuncture, and massage are employed with great frequency.

The medicine of Japan is largely borrowed from China and presents many similar characteristics, but was placed on a more rational basis by a number of physicians from the sixteenth century onwards.

Africa.

In Africa as in the parts of the world already considered disease is ascribed to both human and spiritual agency, but several African peoples show a belief in the production of disease by natural causes to a greater extent than in Austronesia.

The belief in human agency usually takes the form of sympathetic magic, depending on the belief that disease can be brought upon a man by acting upon some part of him. This belief in magic is especially prominent in West Africa and is probably characteristic of the Negro rather than of the Bantu.

Several kinds of spiritual being are believed to inflict disease, but the ghosts of the dead seem to be the most important. In some places a distinction is made between the ghosts of ordinary people and those of chiefs or kings. There is also found the belief in special gods connected with disease and, as in other parts of the world, it is epidemic disease which is especially ascribed to these deities.

The most frequent way in which disease is inflicted takes the form of possession, but the belief in the causation of disease by the absence of the soul or of the life-principle occurs in West Africa.

The motives which are believed to lead ghosts or other spiritual agents to inflict disease are usually the breaking of a taboo, or the neglect to make offerings, tend graves, or perform the rites which the spirits believe to be their due. If the relatives of an orphan do not give the child the social position which belongs to it, it is believed that the ghost of the child's father may inflict disease upon them.

In cases where disease is ascribed to possession by a spirit the natural remedy is exorcism, which is effected either by direct appeal to the spirit or deity, but more frequently by means of a power believed to belong to an object prepared in certain ways, the fetich which is so characteristic of African culture that the term "fetichism" has come to be widely but loosely applied to the whole of African religion. A frequent form of fetich is the horn of an ox filled with various substances to which virtue is imparted by certain rites. Another frequent mode of treatment is to carry out rites designed to transfer the disease, or rather the spirit causing the disease, to some object, such as a tree or animal, or to another human being. In the last case the spirit of the disease is believed to pass into a model of the patient in clay which has been in contact with the patient's body. The object so animated is then put by the roadside or some other place where it will enter the body of the next passer-by.[12] This method closely resembles the form of magic in which a sorcerer inflicts disease upon an enemy, but differs from it in that the African purpose need not be malicious, but disease is brought upon the passer-by in the interest of one who is already ill.

In some cases in which the occurrence of disease follows an offence, such as adultery on the part of a woman while bearing or nursing a child, it is believed that the disease can only be cured by confession and rites of purification.[13]

An important place in African medicine is taken by amulets designed to avert disease. These often resemble the fetiches used for the treatment of disease.

Several African people seem to possess in a definite form the idea of the causation of disease by climatic or other natural conditions, in which case their remedies may be purely medical and devoid of any religious character, though the nature of the remedies usually brings them nearer to those of the Middle Ages than of our own time. This development of a genuine art of medicine has been recorded among several Bantu peoples, but seems to have reached its greatest height among the Masai,[14] who are said never to ascribe disease to the action of spirits and only rarely to human agency. We are told of only one disease, elephantiasis of the scrotum, which is regarded as a punishment for sin.

In addition to the modes of combating disease which are closely related to magic or religion, most African peoples employ remedies of a domestic kind which can be used by all, or measures employed by those who possess the necessary skill but are yet quite distinct from the priests or wizards, who carry out rites which are magical or religious as well as medical. Among the remedies of this kind are blood-letting in the form of cupping, massage, various forms of surgery, and many internal remedies.

Among the Masai the internal remedies are known to all, and it is only surgical procedures which are practised by specialised practitioners. In some parts of Africa a man may have a reputation for success in the treatment of some one form of disease. As was found to be the case in Melanesia, where there has been specialisation of medical function, it has often proceeded along lines different from, and it may be even antagonistic to, those which would promote the separation of medicine from magic and religion.

America.

This continent affords a good example of the intimate relation between medicine and religion, the combination having developed to such an extent that most of the religious rites, rites often very elaborate and prolonged, have as their main purpose the treatment of sickness.

The belief in the production of disease by human agency exists in North America, but it is less important and frequent than in many other parts of the world. When sickness is produced in this way the agent is usually one who has many other functions in addition to those connected with disease.

Sickness is more usually ascribed to the action of ghosts or spirits who act either on account of a natural malevolence or because they have been offended by some lapse on the part of the victim, especially the breaking of a food taboo or failure to follow the many observances connected with childbirth, puberty, menstruation, and coitus.

The most frequent belief concerning the mode of production of disease is to ascribe it to the introduction into the body of some noxious agent which, though apparently primarily of a spiritual kind, is often objectified or personified. A frequent object thus regarded as the immediate cause of disease is a piece of bone, and as frequently an animal, either a worm or insect, or it may be an animal as large as a bear or otter. A less frequent belief concerning the causation of disease is that which we have met elsewhere in which disease is ascribed to the absence of the soul or of one of several souls. Disease may also be assigned to natural causes, such as the action of the moon or of the winds.

As elsewhere, the chief lines of treatment of disease in America are the logical outcome of the beliefs in causation. They consist of rites of exorcism in which the disease possessing the patient is driven away by incantations, the noise of rattles and drums, and other means. In other cases the objectified disease is extracted by sucking or other forms of legerdemain. When disease is ascribed to loss of the soul it is recovered by a leech, and it is sometimes believed that, as in Indonesia and Melanesia, the soul of a leech leaves his body in order to recover the lost soul of the patient. Disease may be transferred to an

animal or to another person. In the highly developed rites of the medicine societies of the Pueblo Indian, the Navaho and Apache, all the members of the society assist in the rites designed to restore health to a sick person, who defrays the whole cost of the ceremonial.

In addition to these lines of treatment which bring medicine into such close relations with religion, a number of measures, including plants as internal remedies, blood-letting, cauterisation, poulticing, massage, and vapour baths, are employed.

The civilised peoples who inhabited Mexico and Central America when these countries were conquered by the Spaniards practised an art of medicine which bore a general resemblance to that of other parts of America, though of a more advanced kind.

Among the Aztecs, of whose medicine the record is most complete, the occurrence of disease was usually ascribed to the gods, though sorcery was occasionally held responsible. An illness was often believed to follow some fault on the part of the patient, usually some breach of ritual. There were special gods of disease. In Mexico they not only inflicted disease, but there were special deities of healing, one such being a goddess of herbs, and another one who had discovered the curative properties of turpentine.

Corresponding with this belief in the divine origin of disease, diagnosis and prognosis often took the form of divination and the course of an illness was foretold by scrying in a mirror or in water or by the unravelling of a knot. The remedies included an extensive pharmacopœia, in which plants predominated, while bleeding, vapour baths, and massage were widely employed. Rites of exorcism were also used, while among this advanced people we meet again the form of treatment in which the leech pretends to suck from the body of his patient a pebble or other object which was held to have been implanted there by human or spiritual agency and to have been the cause of the illness.

Disease was also transferred from one person to another. A figure of dough, made in human form, was placed by the roadside so that it might enter the next passer-by, a process bearing the closest resemblance to one I have already mentioned as occurring in West Africa.

The existing rude peoples of Central America practise similar methods. One tribe of the Mosquito Indians of Nicaragua has the peculiar custom that sick persons are urged to eat as much as possible, especially of green turtle.

In many parts of South America the belief in human agency in the production of disease is especially prominent. Thus, in British Guiana every disease is regarded as the work of a sorcerer and an illness ascribed to his spells is treated by one of a class of practitioner who pretends to extract an object placed in the body of the patient by the sorcerer.[15]

The Incas of Peru had an extensive pharmacopœia and practised venesection, but we do not know that their religious rites were as closely connected with health and disease as was the case among the Aztecs and Mayas. The Mapuche of Chili[16] have two classes of priest, of which one also acted as leeches, while surgeons form still another body of specialised practitioners. Those who were at once leeches and priests are said to be concerned with spirits, to whose action it would seem that disease was attributed. The Mapuche use many herbs and employ venesection, massage, and vapour-baths.

SIMILARITY IN VIEWS ON CAUSATION AND TREATMENT OF DISEASE.

This survey, brief though it be, is sufficient to show how great a similarity exists between different regions of the earth in the general character of the beliefs concerning the causation of disease and in the measures which are used to combat its effects. As I have already said, these similarities have been held by most students of human society to be the result of uniformity in the working of the human mind in response to its environment. They are held to be examples of similarity in the course of evolution owing to similarity of the materials which the process of evolution moulds and uniformity of the agency by which this moulding is carried out. Only when the similarities occur among neighbouring peoples or among peoples who, though distant from one another, are known to have been in contact, has it been customary to explain them by the transmission of culture from one place to another. Otherwise they have been supposed to have arisen independently, and this view is still widely held. Its advocates fail to see how in early stages of his culture man can have moved about the world with sufficient freedom to produce the wide dispersal of object and custom which must have occurred if these similarities are due to transmission. I propose in these lectures to consider the rival views according to which these similarities depend upon transmission or are the result of processes of independent origin.

CONSIDERATION OF RIVAL VIEWS.

I may first point out how favourable a case for independent origin is presented by the phenomena of disease. Many of the similarities of culture which are believed to have come into being independently in different parts of the world relate to features of man's environment which are far from uniform. Thus, different parts of the earth show great differences in the apparent movements of the sun and in the course and nature of the seasons. As great variations are shown in the nature and annual changes of vegetation and in the natural features of land and sea. If the human mind is the same everywhere these differences in the physical environment should lead us to expect diversity rather than uniformity in the customs relating to them. Where we find similarities of reaction towards the sun, the seasons, vegetation, and other natural conditions in places where Nature presents herself under such widely diverse aspects, the advocate of the independent origin of these similarities is met at the outset by a serious difficulty.

This initial difficulty is not present, or is present in much less degree, where man himself is more directly concerned. The phenomena of birth and death are the same everywhere. The difficulty which here meets the believer in independent origin is to explain the great diversity which is shown by man's modes of reaction towards these occurrences of his own life.

This similarity of conditions throughout the world is also presented, though in somewhat less degree, by the phenomena of disease. With our advanced knowledge we recognise a considerable degree of diversity in the diseases of different parts of the world, but in his ruder phases of development man deals with symptoms rather than with diseases, or, more strictly speaking, does so in even greater measure than ourselves. The chief manifestations of disease, pain, fever, disturbances of the digestion, swellings, ulcerations and eruptions, are much the same everywhere and present a body of appearances showing so great a natural similarity that disease offers a most favourable opportunity for the advocates of independent origin. If they fail to show that similarities in the reaction of mankind towards disease have been the result of independent discovery and invention, it is difficult to see where they are likely to succeed.

Two Widely Differing Beliefs in Causation of Disease.

I can only to-day consider briefly two problems suggested by the material laid before you in this lecture and in the lectures of last year. These will serve to illustrate the kind of situation with which we are confronted in this subject.

The sketch I have given of the beliefs and practices of different regions of the earth in relation to disease has brought out certain differences in the distribution of the customs which bring medicine into such intimate relations with magic and religion.

The belief in the production of disease by the abstraction of the soul, of some part of the soul, or of one of several souls, appears to be limited to Indonesia, Papuo-Melanesia and America. We do not know of it in Asia, and though disease may be ascribed to absence of the soul or of the vital principle in West Africa, this belief does not appear to have given rise to the organised system of practices which we find in Indonesia and to a less extent in America.

India and Africa, on the other hand, are pre-eminently the seat of the belief in the production of disease by possession. These two beliefs, one in the production of disease by the addition of something to the body of the patient, the other in the abstraction of something from it, are more or less opposed to one another.[17] If the phenomena of disease are much the same all the world over, and if the similarities of belief and action are due to the uniformity of the human mind, how comes it that men should have been led to these very different beliefs, and why should these beliefs have different distributions?

The advocate of independent origin ought to be able to point to something in the nature of the diseases of Indonesia or in their relation to the environment which led the inhabitants of this region to attach so great an importance to the abstraction of the soul, while the peoples of India and Africa failed to make such a discovery, or, if they believed in the absence of the soul as a cause of illness, failed to make it the basis of their system of therapeutics.

Still more difficult is the task of explaining the co-existence of these widely different, if not opposed, beliefs among one people, as in North America. If, as the majority of students of American ethnography hold, the culture of this continent has been the result of a wholly independent process of development, we should hardly expect to find two such widely different modes of conceiving the essential nature of disease. The coexistence of two such concepts

[15] E. Thurnim: Among the Indians of Guiana, London, 1883, p. 329 et seq.

[16] O. Aichel: Arch. f. Geschichte d. Medizin, 1913, vi., 161.

[17] These opposed beliefs may sometimes be brought into relation with one another. Thus the Ewe-speaking peoples of West Africa believe that when the soul of a person quits his body it provides an opportunity for a wandering, homeless spirit to enter and produce disease. A. B. Ellis: The Ewe-speaking Peoples, London, 1890, p. 107.

s far more naturally explained as the result of the contact of eoples and the blending of their cultures.

This solution of the problem becomes still more natural hen we find the belief in the production of disease by the bstraction of a soul especially frequent and important on ie western side of the American continent—viz., in that art which forms one shore of an ocean on the other side of hich this belief flourishes. Very significant in this con-exion is the condition found among the Songish, whose omen are able to cure disease due to causes other than loss the soul, while a lost soul can only be recovered by one a special class of shamans.

Remedies of the "Domestic" Order.

The second problem which I choose for the purpose of ustration is suggested by certain differences which distin-ish the domestic remedies of many peoples from those nich are, or should be, applied only by persons with pecial qualifications. I showed last year[18] that the means combating disease adopted by the peoples of Melanesia d New Guinea follow naturally from their beliefs concern-g its causation. Once we know the Melanesian or Papuan eory of disease and their diagnostic and therapeutic easures are seen to be only the logical consequences of is theory. Actions which may seem meaningless or even iculous on superficial examination are only the natural tcome of the views which the people hold concerning the ture of disease. I stated, however, that there were excep-ns. It is in the remedies which may be applied by anyone d do not need the services of a specially qualified practi-ner that these exceptions are most apparent.

These remedies correspond very closely with those which ong ourselves we call "domestic," remedies used by yone in cases of slight illness or at the first onset of more ious illness before its gravity is recognised. Just as ong ourselves the doctor is only sent for when nestic remedies fail or when the illness is at once seen be serious, so do the Melanesian, Papuan, and other ly peoples only consult the sorcerer, priest, or leech when ir remedies of the domestic order fail, or when the gravity the case demands more powerful measures.

The nature of these domestic remedies is well illustrated the Kai, a people of North-Eastern New Guinea, of ose prolonged and complex ritual, based on the belief in traction of the soul or soul-substance, I gave so full an ount last year. In addition to the measures which involve activity of the sorcerer or leech, the Kai use a number of edies which seem to have no connexion with the concept oul-substance.

r wounds they use a rude kind of poultice made of the powdered s of the cycas-palm covered with its leaves, and various kinds af or bark are believed to have a healing action upon wounds.
e abstraction of blood is an almost universal remedy. Freshly ted wounds are made to bleed as freely as possible, and unless is done it is believed that the wound will never heal. It is held the bad blood flows away while the good blood remains in the . Headache is treated by cuts on the forehead, made with ters, formerly of obsidian and now of glass. In cases of nasal rh a stick is thrust into the nostrils to make them bleed, and this ment is also used in cases of illness in which the nose is not itself ed. Blood is also drawn by leeches applied to parts of the body h are the seat of pain.
pain in the chest with difficulty of breathing the people stroke hest with a kind of nettle, and this remedy is also used to get the muscular pain which follows long marches or the bearing of heavy loads. Vapour-baths, used for rheumatic pains, are produced ated stones, lying on and covered by leaves, placed in a hole in the earth. The painful part of the body is exposed to apour which rises from the leaves, or steam may be produced by ng hot stones into the coconut vessels which are used to carry . Kneading of the body is sometimes employed. A curious ly is used for deafness due to occlusion of the external auditory is. A small chafer is introduced into the passage and may remain for several days. This method of cleaning what Kevsser calls ugean stable of the Papuan ear, is believed to be highly efficacious restoration of hearing.

is lowly people of New Guinea thus use more or less forms of five modes of treatment which are found y over the earth—viz., poulticing, blood-letting, ige, vapour-baths, and counter-irritation. Moreover, practices stand apart from the system of therapeutics on the belief in the production of disease by human iritual agency which bulks so largely in the minds of eople.

would be easy to point out ways in which each one of easures found among the Kai might have been dis-ed by the process called chance or accident. The whole history of invention shows, however, that new discoveries do not arise in this way, but are the direct outcome of the physical and social conditions in which they have their birth. Even if inventions come to fruition by mere accident it would still be difficult to accept the position that these rude savages discovered independently and by chance five of the procedures of our own mediæval and modern medicine.

If we are to explain the independent origin of these Papuan practices we ought to be able to show that they arose out of the body of beliefs held by the people concerning the nature and causation of disease, and this is just what we cannot do. The Kai have a definite body of beliefs concerning the causation of disease, to which corresponds a definite system of therapeutics, but this system does not include the remedies I have just enumerated, nor does it seem possible to show that these remedies are in any way connected with the dominant beliefs concerning the causation of disease.

Origin of Above Practices.

The survey of the medicine of other parts of the world which I have given in this lecture shows that what is true of the Kai is true of nearly all the more lowly peoples of the earth. When we find such peoples practising venesection and cupping and using massage and vapour-baths, &c., these practices do not form part of the blend of religion and medicine which is the most striking characteristic of the attitude of these peoples towards disease. They are not practised by the special class of persons who combine in various degrees the functions of the priest and the leech, but they may be performed by anyone, or by persons who have acquired a special reputation for skill in these respects by practice and ability, not through the special processes of initiation which are usually necessary for the practice of the rites in which medicine and religion are so closely blended. In many cases even these forms of treatment are exercised by women who are so often rigorously excluded from participation in medico-religious rites.

Most of the peoples of the earth who use blood-letting, massage, and vapour-baths, have certainly not been led to these practices by motives arising out of the ideas and beliefs regarding disease which dominate the larger part of their behaviour in the presence of disease. If they have arisen independently in different parts of the earth they have not grown out of the magico-religious atmosphere which surrounds disease. They must rather be ascribed to some kind of reaction against this religious atmosphere, to a movement on the part of the general body of the people against a view of disease forming part of a system of beliefs which regulate behaviour, not only towards disease, but towards many other aspects of nature. The special arguments against independent origin which each of the customs suggests when examined independently are strongly reinforced by the absence of any relation to the body of beliefs which determine the attitude of the more lowly peoples of the earth towards disease.

It is, of course, open to the advocates of independent origin to say that such practices as blood-letting and vapour-baths as they exist in New Guinea are only the beginnings of a movement towards rational medicine among a people who had till then been altogether dominated by a system of sorcery or priestcraft. They may say that the rude forms in which these remedies occur are natural as the first product of trends of thought which have produced the more elaborate and finished forms of these practices among ourselves. In response to such an argument I will now make only one suggestion.

Highly as we rate our own civilisation, it did not enable us to discover for ourselves practices which, according to advocates of independent origin, must have been discovered by the Melanesian and Papuan. We acquired our practices of bleeding and counter-irritation from the Greeks or Arabs, our massage from the French or other continental people, and our vapour-baths from the Turks and Russians. The civilisation of which we are so proud did not of itself suffice to teach us these remedial arts, but we had to acquire them by contact and mixture with other peoples. If we are to accept the teachings of those who believe in the independent origin of such practices in Africa, Asia, Oceania, and America, we shall have to accept the position that the savage or barbarous peoples who inhabit these continents and islands were somehow able to discover arts which we who think ourselves so greatly their superiors were content to learn from other peoples.

[18] THE LANCET, 1916, i., 122.

ABSTRACT OF A

Lecture

ON THE

RELATION BETWEEN CHEMICAL CONSTITUTION AND PHYSIOLOGICAL ACTION.

Delivered before the Chemical Society on Dec. 6th, 1917,

BY F. L. PYMAN, D.Sc., PH.D.,

DIRECTOR OF THE WELLCOME CHEMICAL RESEARCH LABORATORIES.

THE relation between chemical constitution and physiological action occupies a definite and important place in the study of drugs. Chemical investigation of a drug begins with the attempt to isolate the principle to which its activity is due. Then follow the determination of its constitution and the synthesis of a number of substances more or less closely related to the parent compound and comparison of their physiological action.

EXAMPLES OF EFFECT OF CHEMICAL CONSTITUTION.

The wideness of the term physiological action—covering, as it does, any action on the living organism—renders its discussion difficult. It is impossible, for instance, to compare the bactericidal action of phenol with the hypnotic effect of diethylbarbituric acid or with the anæsthetic action of cocaine. Moreover, the same superficial signs of physiological action may be due to widely different causes. Everyday examples of physiological action are not lacking. Compounds of similar constitution generally possess a characteristic group smell—for instance, the lower fatty acids—whilst each member may have a specific odour, which in this case serves to distinguish the individual members from formic to valeric acids. Sense of taste also provides an occasional means of discrimination, not only between side chains of different length—*p* ethoxyphenylcarbamide being sweet, whilst the higher alkyloxyphenylcarbamides are not—but also in certain cases between stereoisomerides, *d*-histidine, for example, tasting sweet, whilst *l*-histidine is tasteless.

Stereochemical influences often exercise profound effects, particularly on nerve-endings. Thus, *l*-hyoscyamine has about 100 times the mydriatic action of *d*-hyoscyamine, and *l*-adrenaline many times the pressor effect of the dextro-compound. Asymmetry of a nitrogen atom may also condition a difference, as in the case of the α and β methochlorides of *l*-canadine. The cause of this variation still remains in doubt. In one instance—that of β- and ϵ-cholestanol—Windaus has noted that the difference in their power of inhibiting the hæmolytic action of saponins—digitonin, for example—is accompanied by an equally great difference in their ability to combine with digitonin. The close relation of the cholestanols with cholesterol gives special importance to this observation, and it may be that in other cases also the action of stereoisomerides varies according to their ability to combine with the constituents of the nerve cells.

The influence of physical properties, such as solubility in different media, may be of importance, and Meyer and Overton have shown that for a particular series of aliphatic compounds their narcotic effect on tadpoles was proportional to the partition coefficients of their solubilities in oil and water.

An indication of the effect of chemical properties is afforded by the work of Ehrlich, who showed that whilst certain basic dyes stained the grey nerve substance their sulphonic acids did not. This difference suggested that bases, liberated in the blood stream by alkali, are extracted by the nerve substance, whilst their sulphonic acids remain in solution as alkali salts. He also adduced examples showing a change of action when certain basic drugs are converted into derivatives containing free acid groups or into quaternary salts. In the case of alkaloids it is a general rule that the introduction of a free carboxyl group profoundly modifies the physiological action. Benzoylecgonine, of which cocaine is the methyl ester, has no local anæsthetic action; whilst quitenine, obtained from quinine by oxidation of the vinyl group, is non-toxic. Formation of quaternary salts has also a considerable effect. For instance, papaverine has a strychnine-like action which is missing in its methochloride and reappears in its reduction product laudanosine.

FOUR PIECES OF EXPERIMENTAL WORK.

In the many cases in which members of a group of compounds of similar constitution resemble one another in physiological action it is of interest to observe the effect of slight chemical alterations. Four such pieces of work were outlined.

Tropeines.

The group of compounds known as tropeines are acyl derivatives of the aminoalcohol tropine. They were investigated with a view to determining the relation between the chemical constitution of the acyl group and the mydriatic effect produced by the instillation of a neutral solution equivalent in tropine content to a 1 per cent. solution of homatropine hydrobromide into the conjunctival sac of a cat. Six groups were examined, comprising tropeines of aliphatic acids, of substituted benzoic, hydratropic, phenylacetic, and phenylpropionic acids, and of acids in which the carboxyl and phenyl groups are separated by an imino-group.

Consideration of the results led to the conclusion that no sweeping generalisation could be made.

A generalisation associated with the name of Ladenburg, but repudiated by him, states that a tropeine, to have mydriatic properties, must contain (*a*) a benzene nucleus and (*b*) an alcoholic hydroxyl group in the side chain. The first is approximately correct, no aliphatic tropeine having yet been found to possess mydriatic properties in dilute solution, but the closed chain need not necessarily be that of benzene, as β-2-pyridyl-α-hydroxypropionyltropeine is active. The second postulate is incorrect, for mydriatic substances are obtained when the hydroxyl group of atropine is exchanged for chlorine, bromine, or acetoxyl, and when that of homatropine is exchanged for hydrogen, chlorine, or amino, or closed by the formation of a lactone. Quantitatively, however, the tropeines found to be more active than, or equal to, homatropine, contained an alcoholic hydroxyl.

Of the tropeines of hydroxybenzoic acids, the *o* and *m* compounds were active and the *p* and *3:4* compounds inactive. In the case of the methylmandelyltropeines the *p* compound is again less active than the *o* and *m* isomerides.

The tropeines of substituted hydratropic, phenylacetic, and phenylpropionic acids examined were all active, with the exception of atropine- and homatropine-sulphuric acids, the lactone of *o* carboxyphenylglyceryltropeine, and those with an unsaturated linking in the side chain containing the carboxyl group.

The steric structure of the acyl group influences the mydriatic properties—instance *d* and *l*-hyoscyamine—and steric structure is also of importance in the basic portion of the molecule, as the tropyl and mandelyl esters of pseudotropine have no mydriatic properties.

Aminoalkyl Esters.

Aminoalkyl esters possess the general formula $R.CO.O.(CR_1R_2)_n.NR_3R_4$, and are formed by the esterification of an *acid* with an *alcohol* containing an *amino* group. From the collated results of numerous workers the following general conclusions may be drawn as to the constitution of aminoalkyl esters having local anæsthetic properties. The *acyl-group* is generally, but not necessarily, aromatic. It is most often benzoyl, but many derivatives of aminoalcohols containing the *p*-aminobenzoyl, phenylacetyl, cinnamoyl, or *p*-amino-cinnamoyl groups are active. The *amino group* may be secondary or tertiary, and may be associated with simple or bridged ring complexes. The action may be modified by the nature of the alkyl groups replacing the hydrogen atoms of the amino group. The *alcohol* residues are very varied, may be primary, secondary, or tertiary, and may separate the acyl residue and the substituted amino group by chains of either two or three carbon atoms.

Adrenaline and the Amines.

Adrenaline, the active principle of the suprarenal gland, a substance of comparatively simple constitution—β:3:4-trihydroxyphenylethylmethylamine—$(OH)_3.C_6H_3.CH(OH).CH_2.NHMe$. Barger and Dale studied the relation between chemical constitution and sympathomimetic action in a large number of amines gradually approaching adrenaline in constitution. These comprised (*a*) aliphatic amines, the most active of which was *n*-hexylamine; (*b*) aromatic amines

ontaining an otherwise unsubstituted benzene nucleus. Of hese, the most active was β-phenylethylamine, which differs rom adrenaline in that it lacks the 3:4-dihydroxyl substituent in the benzene nucleus, the hydroxyl in the side-hain and the *N*-methyl substituent. The introduction of ither or both of the last two did not lead to more active ubstances. Finally, (*c*) they examined the effect of 1, 2, or 3 ydroxyl substituents in the benzene nucleus. Consideration of ie results obtained led them to conclude that the optimum keleton for sympathomimetic action consists of a benzene ng with a side chain of two carbon atoms, the terminal ne bearing an amino-group. Another optimum condition the presence of two phenolic hydroxyls in the 3:4 position relative to the side chain; when these are present an coholic hydroxyl still further intensifies the activity. A henolic hydroxyl in the ortho-position does not increase the ctivity.

Consideration of a number of glyoxaline derivatives gave gain an optimum side chain of two carbon atoms between ie ring system and the amino group.

Protozoacidal Drugs.

Quite recently experiments have been made on the relative xicity to infusoria of a number of cinchona derivatives, with view to their employment in the treatment of malaria. The sults, which indicated that ethylhydrocupreine was the ost active, do not admit of any certain conclusions as the relation between their chemical constitution and otozoacidal action.

Experiments have also been made on the relative toxicity the ipecacuanha alkaloids to amœbæ. They indicate that e full amœbacidal action characteristic of emetine is only hibited when the nucleus is intact.

FIFTH ANALYSIS OF

ASES OF TETANUS TREATED IN HOME MILITARY HOSPITALS

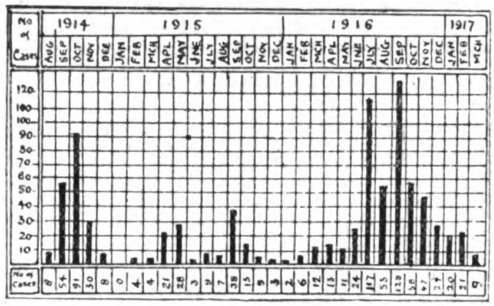
DURING PART OF DECEMBER, 1916, ALL JANUARY AND FEBRUARY AND PART OF MARCH, 1917.

BY SIR DAVID BRUCE, C.B., F.R.S., F.R.C.P.,
SURGEON-GENERAL, ARMY MEDICAL SERVICE.

FOUR analyses of cases of tetanus treated in home spitals have been published in THE LANCET.[1] The mber of cases of tetanus dealt with in the five periods and e rate of mortality are given in Table I.

TABLE I.

Analyses.	No. of cases.	Recovered.	Died.	Mortality.
				Per cent.
-15	231	98	133	57·7
-16	195	99	96	49·2
-Oct., 1916	200	127	73	36·5
-Dec., 1916	100	69	31	31·0
-March, 1916-17 ...	100	81	19	19·0



n the second analysis it was stated that "early treatment uld be striven for, and if this were done and the antitoxin lied thoroughly, one would not despair of reducing mortality to, say, 20 per cent. instead of 50 per cent., which it stands for the past year." The mortality has n reduced to 19 per cent. for the last hundred cases, whether this has been due to the specific treatment, o which of the several factors which come in, it is impose at present to say. Whatever is the cause—the prophyic dose of serum, better surgical treatment, quicker gnosis, more thorough therapeutic treatment, &c.—the ılt is gratifying. It is difficult to apportion the proper rds. For example, if surgical treatment could be made essful, if wounds could be cleaned up and rendered ile at the beginning, then there would be no more cases of nus. There is some evidence that an improvement in gical technique is discernible, but much remains to be e.

(1) THE LANCET, Oct. 23rd, 1915; (2) Dec. 2nd, 1916; (3) June 30th, ; (4) Sept. 15th, 1917.

The Distribution of Cases of Tetanus from August, 1914, to March, 1917.

Diagram 1 merely represents the number of cases of tetanus which have been treated in home military hospitals since the beginning of the war. They are taken from the date of the wound, not from the date of the onset of the

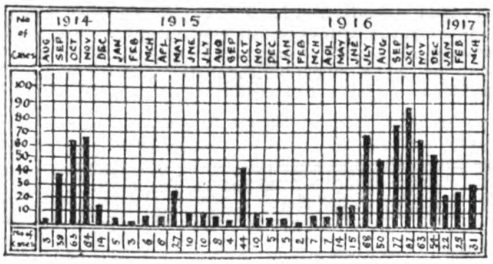


DIAGRAM 1.

disease. In August, 1914, there were eight men wounded who sooner or later developed tetanus. The figures have no relation to the number of wounded or the number of troops engaged. The diagram shows periods of activity and inactivity in the fighting line.

For example, the eight men in August, 1914, were wounded at the battle of Mons, the 54 in September at the

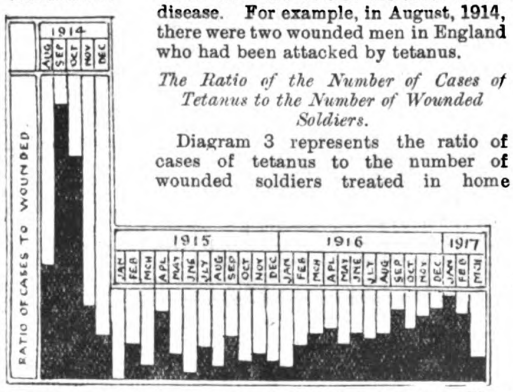

DIAGRAM 2.

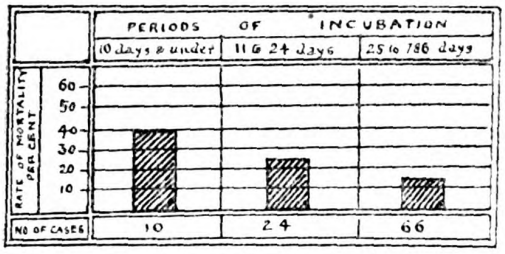
battle of the Marne. The cases in October and November were due to wounds received probably at La Bassée and Ypres. The rise in September, 1915, marks the battle of Loos; in July, 1916, the battle of the Somme, and so on.

Diagram 2 represents the number of cases of tetanus which have been treated in home military hospitals since the beginning of the war. They are taken from the date of the onset of the disease. For example, in August, 1914, there were two wounded men in England who had been attacked by tetanus.

DIAGRAM 3.

The Ratio of the Number of Cases of Tetanus to the Number of Wounded Soldiers.

Diagram 3 represents the ratio of cases of tetanus to the number of wounded soldiers treated in home military hospitals from August, 1914, to March, 1917. They are reckoned from date of wound, not from onset of disease. The abrupt fall in the ratio in November, 1914, is due to



the introduction of prophylactic injections of antitoxin, which took place about the middle of October.

In regard to the proportion of wounded men who contract tetanus in home hospitals it is impossible at present to give accurate figures. The number of wounded in England has not been published. Judging from reports which have come in from various districts it may be roughly put down at 1 per 1000.

Relation of the Number of Days which Elapse between the Date of Wound and the Onset of Symptoms, and the Rate of Mortality.

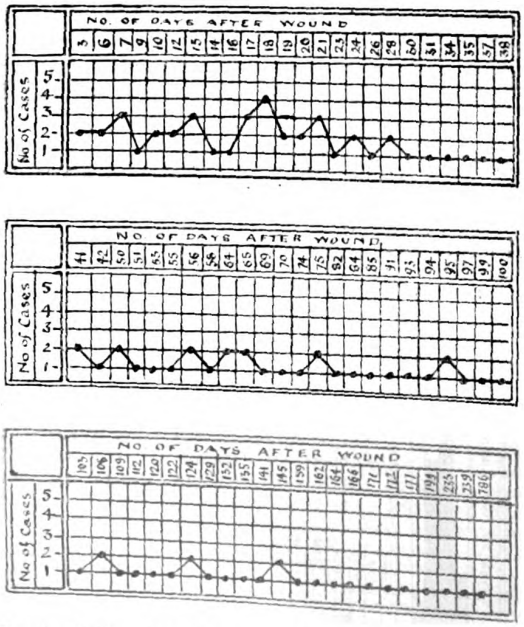


Diagram 4 shows that in the 100 cases dealt with if the symptoms of tetanus appeared within ten days of receiving

DIAGRAM 4.

the wound the mortality was 40 per cent., if from the eleventh to the twenty-fourth day 25 per cent. The remaining 66 cases, with an incubation period of from 25 to 786 days, 13·6 per cent. The incubation period of 786 days is a doubtful case. The man is reported to have had three attacks of tetanus. The last attack, 786 days after the date of wound, was probably due to a nervous hysterical condition which was mistaken for tetanus. As has been shown by Dr. Goadby, the tetanus bacilli may remain for long periods quiescent at the site of old wounds, so that 786 days would not seem to be an impossible incubation period. But in this case it must be left out of count.

CURVE A.

The Incubation Period, or Number of Days which Elapse between the Date of Wound and the Onset of Tetanus Symptoms.

Curve A shows the number of cases which occurred on each day after the date of the wound. The shortest period of incubation was 3 days, the longest 239. The case with an incubation period of 786 days must, as already explained, be ignored. There were only 10 cases with a short incubation period—that is, up to 10 days—and 69 cases with an incubation period of more than 22 days.

The Average Length of Incubation of Cases of Tetanus Treated in Home Hospitals since August, 1914.

Table II. shows that the average incubation period has been steadily lengthening since the beginning of the war. This is probably principally due to the prophylactic injection of antitoxin.

TABLE II.

Analysis.	No. of cases.	Average incubation in days.
1914–1915	231	13·4
1915-1916	195	31·2
Aug.-Oct., 1916	200	30·6
Oct.-Dec., 1916	100	45·0
Dec., 1916-March, 1917	100	67·0

The Variation in the Period of Incubation since the Beginning of the War.

Table III. gives the number, in percentages, of cases with short, medium, and long incubation periods which have occurred since the beginning of the war. From it will be seen that in the first year there were 47 per cent. of cases with a short incubation, whereas in the last analysis this has fallen to 10 per cent. In 1914–15 there were only 6·4 per cent. of cases with a long incubation period; this has risen to 69 per cent.

TABLE III.

Analys's.	Incubation periods.		
	Up to 10 days.	11 to 22 days.	More than 22 days.
	Per cent.	Per cent.	Per cent.
1914–15	47·0	46·4	6·4
1915–16	15·5	48·8	35·6
Aug.-Oct., 1916	14·0	43·8	42·1
Oct.-Dec., 1916	12·6	26·3	61·1
Dec., 1916–March, 1917 ...	10·0	21·0	69·0

This is a measure of the action of the prophylactic inoculations of antitoxin. During the first year of the war many of the wounded did not receive this, hence the number of acute cases with a short incubation.

The Proportion of Cases of Local Tetanus to General Tetanus.

On examining the 100 cases under consideration it was found that 81 could be placed in the general and 19 in the local group. In the 81 cases of generalised tetanus there were 58 recoveries and 23 deaths, a mortality of 28·3 per cent. All the cases of localised tetanus recovered. The symptom of trismus is recorded in 65 out of the 81 cases, opisthotonos in 14. Table IV. gives this in tabular form.

TABLE IV.

Cases.	Type of tetanus.	Recovered.	Died.	Rate of mortality.
81	General.	58	23	28·3 per cent.

Limbs	70	58	12	17·0 „

Among these were 13 cases of trench feet, 4 of whom died.

The Effect of Fractures on the Rate of Mortality in Cases of Tetanus.

In the previous or fourth analysis the percentage of wounds with fracture of one or more bones was 35, with a rate of mortality of 11·4 per cent. It has been held that the presence of a fractured bone complicating a wound was a source of danger and heightened the death-rate. From

Table VI. it would appear that there is little difference in the rate of mortality in the two classes, the slight advantage being on the side of the fractures.

TABLE VI.

Tetanus occurring After Operative Interference with the Wound.

Table VII. gives the cases, 6 in all, in which tetanus is reported to have followed on an operation. There was one death, a mortality of 16·6 per cent. In none of these cases was a prophylactic inoculation of antitetanic serum given before the operation. The Tetanus Committee advise that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should invariably be given.

TABLE VII.

No. of case.	Date of wound.	Date of operation.	Date of tetanus.	Days after wound.	Days after operation.	Nature of wound.	Nature of operation.	Recovered.	Died.
	1916–17	1916–17	1916–17

848	2/11	2/2	4/2	94	2	Both legs, both arms.	Re-amputation.	R	—

There were no cases of operative interference with wounds after tetanus symptoms had appeared in the 100 cases under analysis.

Treatment of Tetanus by Antitetanic Serum.

A. *Prophylactic or Preventive Treatment.*

Among the 100 cases, 73 are noted as having received a prophylactic injection of antitetanic serum in France. Twenty-one cases are reported to have received secondary prophylactic injections; 8 received three injections, 4 received four injections, and 1 received five injections.

Of these 73, 60 recovered and 13 died, giving a mortality of 17·7 per cent. Of the remaining 27 cases, there is no record of prophylactic treatment in 13, although in all probability most of them received it. Of these 13 cases, 11 recovered and 2 died, a mortality of 15·3 per cent. The

TABLE VIII.

Prophylactic injection.	Rate of mortality per cent.				
	1914–15	1915–16	Aug.–Oct., 1916	Oct.–Dec., 1916	Dec., 1916–Mar., 1917

Not recorded ...	41·1	52·0	44·8	40·5	15·3
None given ...	62·5	55·5	54·5	64·7	28·5

remaining 14 cases are stated to have had no prophylactic injection of any kind. Of these, 10 recovered and 4 died, a mortality of 28·5 per cent. This may be represented shortly in Table VIII., which also gives the results since the beginning of the war.

TABLE IX.

No. of cases.	Inoculated.	Recovered.	Died.	Mortality.

In regard to the question as to what influence, if any, promptitude in giving these prophylactic injections has in reducing mortality, Table IX. gives all the available information.

On the Results Obtained from Multiple Prophylactic Injections.—The Tetanus Committee of the War Office have laid down that four prophylactic injections should be given to every wounded soldier at intervals of seven days.

In the 100 cases under review the case mortality was 19 per cent. It will be remembered that only 73 out of the 100 cases were recorded as having received a prophylactic injection in France. Table X. represents the rate of mortality of cases of tetanus which have received one to five prophylactic injections.

TABLE X.

B. *Therapeutic or Curative Treatment.*

The whole of the 100 cases under review were treated with antitetanic serum. 81 recovered, 19 died. Mortality 19 per cent.

On the Influence of Route in the Injection of Antitetanic Serum.—The Tetanus Committee in their Memorandum are of opinion "that in acute general tetanus the best method of treatment lies in the earliest possible administration of large doses of antitoxin by the intrathecal route."

Of the 100 cases—	Mortality per cent.
8 were treated by subcutaneous injections alone. 7 recovered, 1 died	12·5
7 were treated by intramuscular injections alone. 7 recovered, 0 died.	0·0
5 were treated by intravenous injections alone. 5 recovered, 0 died	0·0
2 were treated by intrathecal injections alone. 1 recovered, 1 died	50·0
There were 70 cases which included intrathecal injections. 53 recovered, 17 died	24·2
There were 30 cases which did not receive intrathecal injections. 28 recovered, 2 died	6·6
There were 11 cases which included intravenous injections. 10 recovered, 1 died	9·0
There were 89 cases which did not include intravenous injections. 71 recovered, 18 died	20·2

Is there any other evidence to be found in the tetanus reports that the intrathecal route has any advantage over the other methods of injection?

Treatment Beginning on Day of Onset of Disease.

	Mortality per cent.
During the period December–March, 52 cases were treated with antitetanic serum on the day the symptoms declared themselves. 41 recovered, 11 died...	21·1
Out of the 52 cases the following received antitoxin, but not intrathecally, on the day of the disease. 23 cases: 24 recovered, 4 died	14·2
Out of the 52 cases the following received antitoxin, including intrathecally, on the day of onset of the disease. 24 cases: 17 recovered, 7 died	29·1

Treatment Beginning on the Day Following the Onset of Disease.

During this period 10 cases were treated with antitetanic serum beginning one day after the symptoms had declared themselves. 7 recovered, 3 died	30·0
Out of the 10 cases the following received antitoxin, but not intrathecally, one day after the onset of the disease. 8 cases: 5 recovered, 3 died	37·5
Out of the 10 cases the following received antitoxin, including intrathecally, one day after the onset of the disease. 2 cases: 2 recovered, 0 died...	0·0

Treatment Beginning Two Days after the Onset of the Disease.

	Mortality per cent.
During this period 8 cases were treated with antitetanic serum beginning two days after the symptoms had declared themselves. 8 recovered, 0 died	0·0
Out of the 8 cases the following received antitoxin, but not intrathecally, two days after the onset of the disease. 5 cases: 5 recovered, 0 died	0·0
Out of the 8 cases the following received antitoxin, including intrathecally, two days after the onset of the disease. 3 cases: 3 recovered, 0 died	0·0

Treatment Beginning Three to Eight Days After the Onset of the Disease.

	Mortality per cent.
During the same period 30 cases were treated with antitetanic serum beginning three to eight days after the symptoms had declared themselves. 25 recovered, 5 died	16·6
Of the 30 cases the following received antitoxin, but not intrathecally, three to eight days after the onset of the disease. 11 cases: 10 recovered, 1 died	9·5
Of the 30 cases the following received antitoxin, including intrathecally, three to eight days after the onset of the disease. 19 cases: 15 recovered, 4 died	21·0

It is evident that no case either for or against the intrathecal route can be made out from these figures, and again, as in the last analysis, it would appear better to defer treatment for one or more days after the onset of the disease. This probably only means that the severe cases are treated at once; the less severe are dallied with.

The following tables show the *influence of dosage* on the curative action of antitetanic serum:—

(*a*) *The Total Quantity of Antitoxin Given during the Attack.*

Out of the 100 cases—				Recovered.	Died.	Mortality per cent.
0 received	1,000 units or under.					
5	1,001 to	5,000 units	... ...	5	0	0·0
8	5,001 ,,	10,000 ,,	... ...	5	3	37·4
4	10,001 ,,	15,000 ,,	... ...	2	2	50·0
3	15,001 ,,	20,000 ,,	... ...	3	0	0·0
23	20,001 ,,	30,000 ,,	... ...	17	6	26·0
11	30,001 ,,	40,000 ,,	... ...	11	0	0·0
17	40,001 ,,	60,000 ,,	... ...	15	2	11·6
23	60,001 ,,	100,000 ,,	... ...	17	6	26·0
6	100,001 ,,	249,000 ,,	... ...	6	0	0·0

(*b*) *The Daily Quantity of Antitoxin Given.*

Out of the 100 cases—				Recovered.	Died.	Mortality per cent.
3 received	1,000 units or under	... ...		3	0	0·0
26 ,,	1,001 to	5,000 units	... ...	22	4	15·4
33 ,,	5,001 ,,	10,000 ,,	... ...	30	3	9·0
17 ,,	10,001 ,,	15,000 ,,	... ...	14	3	17·6
7 ,,	15,001 ,,	20,000 ,,	... ...	5	2	28·5
9 ,,	20,001 ,,	30,000 ,,	... ...	5	4	44·4
4 ,,	30,001 ,,	40,000 ,,	... ...	1	3	75·0
1 ,,	40,001 ,,	52,000 ,,	... ...	1	0	0·0

From these figures relating to dosage no useful deduction can be made. They may be useful to enable a comparison to be made with the amount of serum given at different periods during the war.

Other Therapeutic Remedies.

None of the 100 cases under review was treated by carbolic acid or magnesium sulphate.

Conclusions.

1. In the 100 cases of tetanus under review the mortality was only 19 per cent.
2. The incubation period tends to become longer, due to the prophylactic injection. Hence there are only 10 cases reported with an incubation of 10 days or under.
3. Only 14 cases are reported to have received secondary prophylactic injections of antitetanic serum in home hospitals.
4. In regard to the therapeutic effect of antitoxic serum the evidence is still inconclusive.

THE LATE MR. G. A. GLOAG.—George Alexander Gloag, L.R.C.P., L.R.C.S., L.M.Irel., died at his residence at Clifton, Bristol, on Nov. 26th. The deceased qualified in 1868 and had practised for many years in Clifton and Bristol, where he was highly respected. He was formerly on the medical staff of the Bristol Dispensary.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The annual meeting of the subscribers to this institution was recently held. The medical report showed that 666 in-patients had been admitted, against 557 in the previous twelve months. 2353 patients had been treated in the casualty department. The financial statement showed that the expenditure amounted to £5195, and the income was £4148. The adverse balance was £1660. A strong appeal was made for increased subscriptions, or otherwise some of the beneficial work of the charity would have to be curtailed.

A MODERN VIEW OF TETANUS.

BY FRED RANSOM, M.D. EDIN.,

MEMBER OF THE WAR OFFICE COMMITTEE ON TETANUS; READER IN PHARMACOLOGY, UNIVERSITY OF LONDON.

TETANUS is a disease of the central nervous system, and all the effects which tetanus toxin produces are due directly or indirectly to its action upon nerve cells.

Forms of Tetanus in Man and Animals.

Whether all nerve cells are equally susceptible is a point for further elucidation. At a first glance the facts would seem to indicate that certain cells are more easily affected than others. In man, for instance, the muscles of the jaws and neck are usually the first, and sometimes the only, seat of the tetanus spasm. Again, the onset of the disease varies considerably in different animals. Indeed, it is possible to divide animals, including man, into three classes, according to the form in which the disease commences. In guinea-pigs and mice the first symptoms after subcutaneous or intramuscular administration appear in muscles in the immediate neighbourhood of the point of injection, wherever that may be, so, if the toxin is injected into the left hind-leg, the symptoms of tetanus will show themselves first in that limb. This has long been known as local tetanus. In man and the horse certain muscular areas are usually first affected, irrespective of the site of injection—in man the masseters and muscles of the neck, in the horse muscles of the neck and tail. This may be called specific tetanus or tetanus descendens. In frogs and fowls the symptoms are general from the outset.

The further course of the disease depends largely upon the amount of toxin administered. If this has been considerable the local as well as the descending form will develop into more or less severe general tetanus. On the other hand, if the dose of toxin is small no such accession takes place and the attack will not pass beyond the local or specific phase.

Local tetanus does not occur after intravenous injection, but in guinea-pigs and other animals of that group after intravenous injection the neck and jaws are often first affected, and in rabbits the injection of large doses into muscle-free tissue gives rise to tetanus descendens beginning in the jaws. In a general way, in animals the incubation period is longer with small than with large doses of toxin, but no dose, however large, given subcutaneously or intramuscularly will reduce the incubation period below a certain limit which varies with different animals—e.g., for mice 8–12 hours.

Results of Experimental Work.

One of the most striking and interesting of the above facts is the occurrence of local tetanus; for here we have a toxin whose effects are due exclusively to its action on the central nervous system, and yet, in certain animals, the area in which the first symptoms appear is conditioned by the locality of the injection. Until comparatively recent times this problem remained unsolved, and in consequence the etiology of tetanus was obscure. The solution now very generally accepted is that suggested by Professor H. H. Meyer and myself, and is based entirely upon experimental work. The preliminary stages and the conclusive results of the investigation may be briefly summarised as follows.

When tetanus toxin is injected subcutaneously it begins at once to pass from the lymph spaces into the lymph vessels and can, after a few minutes, be recognised in the lymph of the thoracic duct. By this route it reaches the blood stream, not much being taken up by the blood-vessels direct from the seat of injection. The distribution then goes on till, in about 24 hours, the lymph and the blood contain per cubic centimetre about the same amount of toxin. If the toxin is given intravenously it soon begins to pass into the lymph, and again after some 24 hours the thoracic lymph and the blood serum contain per cubic centimetre nearly equal quantities of toxin. Neither after subcutaneous nor after intravenous injection can toxin be detected in the cerebro-spinal fluid, not even when very large doses of toxin far exceeding the minimal lethal dose have been given. If by means of lumbar puncture the toxin is injected into the subarachnoid space without injury to the pia or cord it passes rapidly into the blood stream, and after the usual period of incubation general tetanus ensues. If, however, the toxin is injected intravenously and immediately afterwards the spinal cord is injured by the injection

of a drop of normal salt solution, then the general tetanus is preceded by a local tetanus in the muscles corresponding to the injured segment of the cord. If the injection of toxin is made direct into the cord a local tetanus corresponding to the injured cells ensues, and the period of incubation is greatly shortened. If an animal is first protected by the administration of a large dose of antitoxin so that no free toxin can exist in the blood, and then a small dose of toxin is injected into a motor nerve, a local tetanus corresponding to the distribution of the injected nerve results. Injection of toxin into a purely sensory nerve does not cause either local or general tetanus.

From these and other facts we have drawn the conclusion that the transport of toxin to the central nervous system takes place along the motor nerves The cells of the central nervous system do not pick up the toxin from the blood or the lymph; the only route by which cells can be attacked is viâ the motor nerves. Under this condition the motor nerves of the infected area are at an advantage, and the toxin travelling along them reaches their centres before the rest of the toxin, which has first to be absorbed and distributed, has time to become effective. The consequence is that, other things being equal, the first symptoms of tetanus occur in the area supplied by the motor nerves about the point of injection—a local tetanus arises.

It was further found possible to protect certain areas by injecting antitoxin into the motor nerve. An animal was given intravenously considerably more than the minimal lethal dose of toxin. A few hours afterwards antitoxin was injected into both sciatic nerves. The animal developed tetanus in the muscles of the fore-limbs, head, neck, and trunk, but the hind-limbs remained free. The toxin when it has reached the cord wanders from segment to segment along the nerve tracts, and hence it is possible after an injection has been made into a hind-limb to protect the front part of the body by dividing the cord. For example, two animals were taken. In the one the cord was divided at the 2–3 lumbar vertebra. Each then received toxin in both sciatic nerves. As soon as local tetanus appeared both animals were given a large dose of antitoxin, neutralising all toxin in the blood and lymph. The animal with undivided cord got general tetanus; in the other the tetanus remained localised in the hind-limbs.

The sensory nerve trunks are not implicated in the transport of toxin from the seat of infection or the blood stream to the central nervous system. Nevertheless, sensory cells are susceptible if the toxin is brought into immediate contact with them. Injection into a posterior root does not cause any muscular rigidity, but there is extreme hyperæsthesia in the sensory areas corresponding to the injected root. We have called this condition *tetanus dolorosus*. These further facts indicate not only that the toxin travels in the motor nerves, but also that the transporting medium is not the lymph stream, but the protoplasma of the neurons, for otherwise the occurrence of motor tetanus without *tetanus dolorosus* seems inexplicable, but some observers believe in transport by the lymph.

Symptoms of Tetanus: Course of Events.

The characteristic symptoms of tetanus are: an increased muscular tone, resulting in more or less rigidity and stiffness and some consequent limitation of motility; increased reflex excitability; a condition of contracture, not simply increased tonus, but an absolute shortening of the muscles involved.

The progress of events seems to be: the toxin travelling along the motor nerves reaches the corresponding motor cells and sets up there a certain over-excitability, so that the usual normal reflex impulses which maintain the normal muscular tone become more effective, the tone of the muscles concerned is increased, they acquire a more or less distinct rigidity (stiffness), and freedom of movement is diminished. This is in animals the first symptom of tetanus, and with small doses of toxin nothing further may occur; there is no increased reflex, and the whole symptom may pass off in a day or two or even in a few hours.

If the dose of toxin has been somewhat larger its action extends to receptor cells in the reflex arch in immediate connexion with the affected motor cells; they become over-excitable, so that tactile excitement of the affected (tetanic) limb causes increased response in that limb, but not elsewhere. In animals a flexion reflex is thus often converted into an extension. In the jaws of man this increased reflex excitability causes the inhibitory impulse which is necessary to open the jaws to be converted into an augmentor impulse closing them. If, as happens not infrequently in human beings, the diaphragm is very early attacked (before the jaws), then respiration will be to some extent interfered with because the inhibitory relaxation of the muscle tends to be converted into a contraction (pain in the chest). For a similar reason, if the muscles of the soft palate and glottis are early affected, difficulty in deglutition may be, and, in fact, often is, a very early symptom. Often before the exaggeration of the reflexes becomes excessive there are frequent clonic contractions, twitchings, of individual muscles in the vicinity of the point of injection or the infected wound, indicating increased reflex excitability. After large doses of toxin more and more motor cells and more reflex apparatus in the cord gradually become affected; there is a general rise of muscular tone and general increase of reflexes.

Very soon after, possibly simultaneously with the occurrence of rigidity from increased tonus a certain amount of contracture may be noticed. If at this period the animal is deeply anæsthetised a great part of the rigidity disappears—i.e., is neurogenous, but the relaxation is not complete. A change has taken place in the muscles themselves; there is absolute shortening, contracture, in addition to the raised tonus. This contracture is primarily neurogenous and secondarily myogenous. It resembles the contracture of ankylosis which does not take place if the nerves are divided before the limb is fixed. It varies in degree from slight rigidity to marked contracture of whole groups of muscles—e.g., both hind-limbs. Animals mostly gradually recover, but sometimes the muscles atrophy and the condition becomes permanent.

Certain early symptoms in man are doubtless due to specific sensibility of certain central cells causing localised muscular affection. Epigastric discomfort indicates raised tonus or spasm of the diaphragm. Pain or difficulty in swallowing is associated with increased reflex excitability of the *tensor veli palatini* and *tensor tympani* muscles and the muscles of the glottis; the two former are also associated with yawning, which has occasionally been noted as an early symptom of tetanus. Twitching or painful tenseness in the vicinity of the wound is an early and very suggestive symptom of increased reflex excitability.

Effect of Prophylactic Use of Antitoxin.

The severity of an attack of tetanus depends primarily upon the amount of toxin absorbed, though the possibility of predisposition cannot be denied. Other things being equal, the occurrence of purely local tetanus in man would indicate that the amount of toxin circulating in the blood is small and not sufficient to affect even the specifically susceptible centres for the masseters, &c., though enough has been taken up locally by the motor nerves near the infected area to cause local tetanus. On the other hand, if trismus occurs as an early symptom, or if the diaphragm is affected, the prognosis is not so favourable because it indicates a larger dose of toxin.

However, all this is profoundly modified by the prophylactic use of antitoxin. Previous to the use of antitoxic serum local tetanus as an early stage of the disease in man was, at any rate, seldom observed; since the serum has been used generally as a prophylactic many cases of local tetanus have been recorded. The prophylactic application has tended to remove man from the class of animals predisposed to descending tetanus to that in which local tetanus prevails. This may be interpreted to mean that the prophylactically injected serum, by completely or to a considerable extent neutralising any toxin which may reach the lymph or the blood, protects the specifically susceptible cells for the masseters, &c. It does not necessarily prevent the occurrence of local tetanus, because some of the toxin formed at the point of infection is rapidly taken up by the motor nerves in the vicinity and can then be effective. It has been shown experimentally that the previous injection of even large doses of antitoxin does not prevent the outbreak of local tetanus, though it can, and does, hinder the development of general tetanus.

It is highly probable that under present conditions the occurrence of trismus as a first or early symptom in man is an indication of insufficient or ineffective use of antitoxin as a prophylactic.

Therapeutic Use of Antitoxin.

With reference to the therapeutic use of antitoxin, it must be remembered that the toxin in nerves and nerve cells is inaccessible to antitoxin. The only toxin which can be

effectually neutralised is that in the blood and lymph. Antitoxin is transported by the lymph and the blood; it is not taken up by the nerves, and there is no reason for thinking that it ever gets into nerve cells. It does not pass in any large proportion into the cerebro-spinal fluid after intravenous injection. Even in highly immunised animals the antitoxin in the cerebro-spinal fluid is more than a hundred times less per cubic centimetre than in the blood. Naturally, antitoxin injected into the subarachnoid space would neutralise any toxin which might be there. Moreover, as antitoxin passes very rapidly out of the cerebro-spinal fluid into the blood stream, it would, if in excess, neutralise any toxin in the circulation.

The therapeutic use of antitoxin is, however, fully justified, nay, imperative, because in any given case it is impossible to say whether the toxic dose already in the nervous system is or is not a fatal one; the prompt use of antitoxin may neutralise just that last amount of toxin in the blood which, if it had got into the nervous system, would turn the balance against the patient.

The great question still undecided is how best to apply the antitoxin therapeutically. The answer can only be given after detailed examination of a large number of carefully classified cases. In the therapeutic use of antitoxin everything depends upon time, and hence the immense importance of careful search for the earliest symptoms and the unhesitating employment of serum upon their recognition.

ANALYSIS OF 102 CONSECUTIVE CASES OF TETANUS

TREATED AT SIR J. J. HOSPITAL, BOMBAY, INDIA, FROM OCTOBER, 1915, TO JULY 31ST, 1917.

BY NAVROJI ARDESHIR COOPER, B.A., B.HY., M.D. BOMBAY.

IT will, I think, not be out of place to say a few words as to how this disease is regarded here by the poor and ignorant classes.

Nature of Cases and Results of Treatment.

All the tetanus cases that came under my treatment belonged to the labouring classes, who are generally very poor, illiterate, and completely ignorant of the grave nature of the disease; further, they are highly superstitious. As a class they do not, in most cases, come to the hospital for prompt treatment as soon as tetanus occurs, for it appears to be their common belief that this disease is the outcome of the wrath of some evil spirit or witch. Naturally, therefore, in accordance with their custom, they invoke the help of the gods and goddesses by propitiation and religious offerings through the so-called professional "magicians," whom these highly credulous people believe to be experts in the cure of this disease. Moreover, they seem to suppose that these persons possess the necessary physical and hypnotic control over the evil spirits, who, it is imagined, cause this disease. Thus it is that they suffer the "magicians" to do all sorts of things and even at times to strike the patients ruthlessly in order "to cast off spirits" from their bodies. The result is that they are not brought to the hospital for treatment until their condition has become either worse or hopeless. Out of 102 cases treated during the period of nearly two years, 27 died within a few hours after admission. All these 27 cases were not seen by me, as they were admitted after I had left the hospital for the day.

Of the remaining 75 cases (see Table I.), two had to be discharged against advice, 42 recovered, and 31 died, as follows:—Died within a few hours, 4; within 24 hours, 9; within 48 hours, 7; within 3 to 5 days, 5; died of pneumonia (food), 2; died of hyperpyrexia, 1; died in 6 to 7 days, 3.

Under the treatment described below some of the worst cases have yielded very readily—cases occurring a few hours to a few days after infection, accompanied by very severe spasms and intense agonising pains in the muscles, &c., and with but short remissions between the spasms. The results have been so encouraging that I place them before the medical profession in the hope that attention, particularly of medical men in charge of tetanus hospitals, may be drawn to the combined treatment.

I cannot but point out here some inconveniences. First comes the unsuitable position of the tetanus wards. The arrangements to exclude light and air are poor. Noise is heard at times the whole day from an iron workshop about a dozen yards away, and morning and evening numbers of bullock carts pass near the wards. Secondly, there are too frequent changes of nurses, who are at times removed when they have begun to be useful, and new ones have to be trained. Last, but not least, is the difficulty of getting the required drugs (at times even simple drugs), let alone the antitetanic serum and the necessary apparatus. In spite of all this, I have been able to achieve results which appear to be the best hitherto obtained here, and I presume that my treatment, if judiciously made use of, may produce still better results.

TABLE I.—*Method of Treatment of 75 Cases with Results.*

1. Treatment by drugs—e.g., sedatives and hypnotics.

Total cases.	Died.	Recovered.	Mortality %	Recovered %
16*	9 (6 most severe. 2 very severe. 1 severe.)	7 (1 very severe. 5 not severe. 1 chronic.)	56·2	43·7

* 1 discharged against advice (was improving).

2. Treatment by carbolic acid injections, sedatives, and hypnotics.

12	8 (4 most severe. 1 very severe. 3 severe.)	4 (2 very severe. 2 severe.)	66·6	33·3

3. Treatment by carbolic acid injections, antitetanic serum, sedatives, and hypnotics.

4	2—very severe.	2 (1 severe. 1 not severe.)	50·0	50·0

4. Treatment by antitetanic serum, sedatives, hypnotics, and chloretone rectal injections.

20†	8 (1 most severe. 6 very severe. 1 severe.)	12 (2 severe. 1 chronic. 6 not severe. 3 very severe.)	40·0	60·0

† 1 very severe (discharged against advice).

5. Treatment by chloral hydrate intravenously, sedatives, hypnotics, and chloretone enema injections.

4	2—very severe.	2 (1 very severe. 1 not severe.)	50·0	50·0

6. Treatment by antitetanic serum, chloral hydrate intravenously, sedatives, hypnotics and chloretone rectal injections. (Special combined treatment.)

17	2—very severe.	15 (2 most severe. 7 very severe. 6 severe.)	11·7	88·2

All these 102 cases had never had a dose of prophylactic antitetanic serum.

The results of the tetanus cases treated at the J. J. Hospital (as per hospital registers) from 1910 are given in Table II.

TABLE II.—*Tetanus Cases at J. J. Hospital from 1910-17.*

Years.	Cases treated.	Died.	Recovered.	Otherwise.	Recovered, per cent.
1910–1911	45	33	9	3†	20·0
1912–1913	70	40	23	7‡	32·8
1914–1915, up till September ...	78	48	29	1§	37·9
1915, October, to 1917, July ...	102	31	42*	28	43·0

* 1 discharged against advice (was improving). † 1 discharged as requested, 2 no notes as to what became of them. ‡ 6 no notes, &c., 1 discharged in one day as cured? § 1 no notes, &c. ‖ 27 not seen, 1 discharged against advice (very severe).

It will be seen that the admissions are increasing every year and also that there is a corresponding improvement in the recoveries. Yet I feel sure that better results will be secured in future if greater facilities are afforded to the medical officer in charge of these cases.

Clinical Remarks.

My own experience in the use of antitoxin as a prophylactic is nil, for I have never had a chance of using it as such. However, the various reports speak very highly of it if properly given and in sufficient doses, combined with necessary drugs, injections, &c., together with proper nursing.

I have noticed in a few cases very persistent spastic rigidity of the wounded limb with tetanic spasms. This rigidity remained for days together, though the spasms stopped after a few days. In two cases of spastic rigidity of the wounded limb I noted the relaxation in it after intranervine injections of antitetanic serum. In one case of trismus, treated with drugs only, there was no improvement for days together, until two intravenous injections of antitetanic serum produced the desired effects. Purely local tetanus cases I have never had occasion to see, but a case with trismus of the jaw did occur in my experience with fatal results within a few hours. The patient had a wound in the chin and was intensely anæmic.

The mortality in tetanus cases increases with the involvement of higher centres and the earlier appearance of the disease after infection.

The symptoms are produced according to the parts of the nervous system involved.

The most susceptible centres that suffer earliest are those of the pons and medulla. When the site of infection is near the cranial nerves they suffer directly and early, or sometimes through the blood stream in an indirect way. Hence the antitoxin that circulates in the blood acts better in protecting the higher centres from further damage to them than the spinal ones directly accessible from the wound. Here, therefore, comes the importance of intravenous injections of antitetanic serum in tetanus cases.

Many of my tetanus cases had no evidence of any injury on their bodies, though some of them were cases in their worst forms. The explanation for this is that those patients had been injured weeks or months ago, but that the bacillus or spore implanted in the wound did not germinate into a number of bacilli with production of toxin for a very long period, though the wound healed up completely, until it found favourable conditions for its growth. Hence the so-called idiopathic cases of tetanus.

Details of Treatment.

In a fairly developed adult patient with severe form of tetanus I give the following treatment:—

℞ Chloral. hydrat. ... ... gr. xx	℞ Chloretone ... . gr. xxx
Pot. bromid. .. .. gr. xx	Olive oil... ... ... ʒ iv
Tr. digitalis ... ... m. x	Per rectal injection twice a day.
Tr. hyoscyami ... ... m. xx	℞ Calomel ... ... gr. v
Spt. chloroformi... ... m. x	Sod. bicarb. ... ... gr. x
Aq. chlorofor. ... ... ʒ i	One at bed-time when required.
Every four hours.	

About 30 to 40 c.c. chloral hydrate, 5 per cent. sterilised, intravenously daily until sound sleep is produced and spasms become less.

Antitetanic serum 3000 units or more intravenously daily until the spasms have stopped. Sometimes with very severe spastic rigidity it is given for a few days, though in small quantities.

Chloral hydrate intravenously and chloretone per rectum are given daily, until contra-indicated. When they produce detrimental effects on the heart, or the heart sounds become feeble or the patient becomes very low they are completely omitted and the mixture too is changed by the replacement of chloral hydrate and pot. bromide by ammon. bromide, caffein. citras, &c. Alcohol, pituitrin, adrenalin, morphia, camphor and olive oil, &c., are given by mouth or by injections as required. Other complications are treated on ordinary lines.

Bombay.

CORNWALL COUNTY COUNCIL AND TUBERCULOSIS.—The Cornwall County Council has decided to equip and maintain Tehidy mansion as a sanatorium for tuberculosis, provided the residents of Cornwall will purchase the property and present it as a "war memorial" to the county council. The Tehidy estate, comprising 250 acres, can be purchased for £10,000. The scheme has been warmly taken up, £7000 have been already subscribed, and there is no doubt but that the whole of the sum required will be raised.

THE LATE DR. F. E. WALKER.—Frederick Edward Walker, M.B., B.S. Lond., whose death occurred on Dec. 7th, at Uxbridge, at the age of 43 years, served as civil surgeon during the South African war, attached to the 3rd Durham Light Infantry, receiving the Queen's medal and three clasps. In addition to the work of a busy general practice, he held posts on various public bodies. He was a member of the urban district council and captain of the local fire brigade. Dr. Walker leaves a widow and two young children.

ON CERTAIN FORMS OF ALBUMINURIA AND POLYURIA: THEIR CAUSE AND CURE.

BY EDGAR F. CYRIAX, M.D. EDIN.,
VISITING PHYSICIAN, SWEDISH WAR HOSPITAL, LONDON.

DURING the last few years a good deal has been written on the subject of two varieties of albuminuria—namely, the lordotic and the orthostatic—and on functional polyuria, and various theories have been put forward as to the cause of these conditions. Most observers are agreed that there must be faulty innervation of the nerves of the kidney, either in the form of vaso-motor disturbance or neurosis of the abdominal sympathetic. But no one, as far as I know, has been able to advance any explanation as to why such nerve derangements should result and persist.

Causation.

I have examined a considerable number of such cases, and have come to the conclusion that in many of them the *original* cause of the albuminuria or polyuria is to be looked for in irritability of varying intensity, causing persistent contraction, of certain of the muscles in the renal area—i.e., psoas, erector spinæ, and, to a less extent, the quadratus lumborum.

The method by which these muscular contractions produce disturbance in the kidney function is by irritation of the renal sympathetic nerves, either directly through the psoas and quadratus on which these nerves lie, or indirectly through the erector spinæ affecting the posterior dorsal nerves. The connexions between the latter and the kidney have been studied anatomically, physiologically, and therapeutically.

This theory of muscular irritability also explains why the recumbent position brings about improvement in the albuminuria or polyuria, as the case may be. It does so by causing a greater or less degree of relaxation in the contracted muscles, whereby the irritation of the renal sympathetic is proportionally reduced. Incidentally also the theory of psoas contraction as a cause of lordotic albuminuria explains how, when the recumbent position has removed the albumin, it sometimes reappears when a cushion is placed under the lumbar vertebræ so as passively to reproduce the lordosis. This latter position causes elongation of the psoas, and this in its already irritated state is sufficient to cause it to contract, a state of matters which would not obtain in normal subjects.

These irritative muscular states may be primary, and are then generally of rheumatic or traumatic origin, or secondary to articular, ligamentous, or cartilaginous disturbance in the vertebræ; the spinal column can be affected by joint synovitis, slight displacement of bones or cartilages, just as joints elsewhere.[1]

This leads me to say a few words from the view of cause and effect about visceral disease and their "referred pains." At the present day, if a tender spot be found in any spinal area corresponding to a particular viscus, the tendency is to take it for granted that the tender spinal area is a "referred pain," and is secondary to the visceral lesion. I consider that not infrequently the opposite is the case—i.e., that these pains are not "referred," but are really the manifestation of the cause, or one of the causes—namely, irritated erector spinæ states. Of course, in advanced cases vicious circles are easily, in fact usually, set up.

Illustrative Cases.

The identification of these muscular contractions as one of the exciting causes of certain forms of kidney disease is, of course, of value therapeutically, as one of the important factors in cure or amelioration is the removal of such contractions. The effect of limiting the treatment to this alone can be seen in the two illustrative cases, both of officers treated in the Swedish War Hospital, though I must add that I nearly always in addition employ kidney vibrations, frictions on the nerves in the affected area, active exercises, &c., according to the methods of the late Henrik Kellgren, as thereby the best results are obtained.

CASE 1.—Lieutenant ——, aged 48, was admitted on Jan. 28th, 1917, suffering from the after-effects of an attack of hæmaturia.

[1] Cyriax, Practitioner, 1916, xcvii., 464-471.

History.—On Dec. 16th, 1916, he had a severe attack of hæmaturia which lasted for four days, after which it subsided. He had a continual desire to micturate and had actually to do so every half hour. The blood was mixed with the urine and was of a bright colour. There was no pain or swelling. In spite of the attack, however, he remained on duty in the trenches until Dec. 22nd, when he felt so weak that he had to stop and report himself sick. He was sent down to hospital and put to bed for a week. At the end of this time there was no longer any blood in the urine, but the frequency of micturition was very much increased, necessitating evacuation of the bladder about every one and a half or two hours during the day and two hours during the night. There does not appear ever to have been any albumin. The urine was increased in amount; the notes of the case while still in hospital in France showed the average amount per diem from Jan. 10th to 16th to have been 105 ounces. From the same notes it appears that the specific gravity of the urine as estimated on Dec. 31st was 1010.

Examination, Jan. 27th, 1917.—The patient complained of general weakness, part (but by no means all) of which he considered to be due to his nights being disturbed by frequent calls for urination. There was no actual tenderness on pressure over the kidney itself, but a good deal over the erector spinæ close to the middle line in the lower dorsal and lumbar region. These muscles could be seen to be very rigid and contracted. When lying flat on his face on a couch, these muscles only slightly relaxed, and efforts by gentle pétrissage or passive lumbar dorsiflexion by raising the shoulders to cause entire relaxation were quite unsuccessful. When placed on his back, passive flexion of the hips and knees (i.e., attempting to bring the patient's knees up to his chin showed great limitation of range, pointing to diminution in the amount of extension of the lumbar vertebræ, and induced a feeling of great tension in the patient in his lower dorsal and lumbar region. When he stood erect some lordosis was visible; this quite disappeared when he lay down.

Urine.—He micturated about 8 to 10 times during the course of the day and about 6 times during the night. There was increase in the actual amount (see below), specific gravity 1010, no blood or albumin. The urinary condition had been practically without change during the last four weeks. Blood pressure: maximum 116, minimum 70, as estimated with Martin's Riva-Rocci apparatus. Pulse somewhat irregular.

Treatment.—This was commenced on Jan. 29th; inasmuch as I considered that the kidney condition was entirely dependent upon the muscular contractions, I limited it to mechano-therapeutics in order to remove them (i.e., passive rotations of the lumbar region when the patient was lying on his side, passive flexion of the hips and knees when he was lying on his back, and pétrissage of the muscles, applied very gently at first. Inasmuch as no vibrations, nerve frictions, or abdominal pétrissage was employed, the direct effect on the kidney itself was to all intents and purposes nil, the treatment having its sole effect upon the contracted muscles. The treatment was applied four or five times a week until April 26th, the total number being 56.

Progress.—Feb. 3rd: the erector spinæ contraction is diminishing. Feb. 5th: the frequency of micturition has commenced to decrease. From this date onwards steady improvement in the symptoms. As regards the frequency of nocturnal micturition: Feb. 5th–7th, 5 times; Feb 8th–9th, 4 times; Feb. 10th–18th, 3 times; Feb. 19th–March 22nd, 3 to 4 times; after that, twice. As regards the amount of urine passed: Feb 12th, 120 ounces; Feb. 15th, 87 ounces; March 7th, 76 ounces; March 10th, 60 ounces; March 29th, 52 ounces.

On March 30th the patient went to a convalescent home until April 27th; during this interval the treatment was applied as usual.

A sample of urine taken on March 25th showed the specific gravity to be 1018; no blood or albumin. Ever since March 5th the patient declared that he felt very well, better, in fact, than for several years past.

At the conclusion of the treatment the contraction in the erector spinæ had quite disappeared, and there was no longer any of the limitations of movement mentioned above. Very little change in the condition of the lumbar curve when lying down, but considerable diminution when standing up.

Blood-pressure readings the same as before; no irregularities of the pulse.

Subsequent progress.—On July 18th I heard that the improvement in the urinary condition had been fully maintained since I last saw him.

CASE 2.—Lieutenant ——, aged 23, was admitted on May 13th, 1917, suffering from the effects of contusion of the back.

History.—On May 6th two shells burst in rapid succession near him; the first caused a quantity of earth to be projected against his back and the second one buried him. When he was unearthed he was very dazed and shaken; his back was very stiff and gave him great pain. On May 13th he came to the hospital and on examination I found all the signs of a contused back from sacrum to the upper dorsal region—i.e., rigidity, pain, great tenderness on pressure, inability to lie on his back or to remain long in any position, &c. Some slight discolouration due to bruising was still visible. A skiagram taken of the back was negative. I recommended mechano-therapeutics for his back, but owing to a sudden influx of cases and temporary shortage of workers this could not be commenced for a few days; pending its application rest was prescribed.

The patient improved until May 21st, when he complained of feeling weak. Dr. C. Westman, the resident surgeon, tested the urine and found a trace of albumin; on testing the blood pressure with Martin's Riva-Rocci apparatus, he found the readings were 148, 83. Strict rest in bed and light diet were enjoined. The following day there was the same amount of albumin, and the blood pressure was 148, 82. The next day (May 23rd) there was a much larger quantity of albumin, which was found the next morning to be 2·8 per cent., and the pressure was 160, 88.

I therefore decided to commence the special treatment at once, acting on the same theory as mentioned under the first case. It was accordingly applied on the morning of May 23rd and proceeded with daily until the patient's discharge on June 21st. At first (until May 27th, on which day the albumin disappeared) it was limited to passive movements applied to the erector spinæ in order to reduce the pain and rigidity; on and after May 27th abdominal pétrissage was added.

The immediate effect of the treatment was a great diminution in the pain and tenderness in the erector spinæ, and as regards the albumin only a trace was found in the 24-hour specimen on May 24th, 25th, and 26th; on and after May 27th not even a trace was detected. On May 26th there was no more rigidity in the erector spinæ, and no tenderness on pressure. On May 28th the patient was allowed to get up, and on June 4th he was permitted to go for a short walk. On June 8th ordinary diet was resumed. On June 12th he left the hospital, as he was quite well. The blood pressure on June 11th after an hour's walk was 138, 100.

I wish to express my thanks to the medical committee of the hospital for permission to publish the above cases, and to Dr. Westman for all the work in connexion with the urine analysis.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

An Attempt at the Experimental Production of Carcinoma by Means of Radium.—Explosive Phenomena in Gunshot Injuries.

A MEETING of this section was held on Dec. 4th, Professor W. BULLOCH, the President, being in the chair.

Dr. W. S. LAZARUS-BARLOW showed microscopic slides and a considerable number of lantern slides from rats and rabbits, in which he had endeavoured to produce carcinoma experimentally. In the case of the rat minute tubes containing radium in amounts of the orders 10^{-5} to 10^{-1} mgr. (calculated as element) were introduced beneath the skin. These experiments were undertaken on the basis of the facts that exposure to X rays caused squamous-cell carcinoma of the hand, and that small quantities of radium had been demonstrated by him to be of frequent occurrence in carcinomatous tissue. In the case of the rabbit small gall-stones obtained from the human subject and proved to be devoid of radium by alpha-ray electroscopic analysis were artificially impregnated with radium and introduced into the gall-bladders of the animals. These experiments were based on the fact that he had found a marked difference between the radium content of gall-stones in man according as they were associated with cancer of the gall-bladder or not; gall-stones associated with cancer of the gall-bladder contained relatively large quantities of radium, whereas gall-stones associated with cancer of other parts, or unassociated with cancer, contained mere traces of radium or none could be detected. The experiments were commenced in May, 1912, and were not yet complete. He had not succeeded in producing in the animals the clinical condition known in man as cancer, but in the skin of rats he was able to produce, by means of suitable doses, an irregular, considerable overgrowth of squamous epithelium which sent processes into the corium, was frequently supplied with well-marked cell-nests and was indistinguishable histologically from a very early squamous-cell carcinoma in man. This condition could be produced at will, but if the action of the radium persisted the newly formed cells came under its destructive influence, and if the radium were removed the skin condition receded with some rapidity, leaving merely a thin scar tissue devoid of hair and hair follicles. The gall-bladder of rabbit experiments showed a more advanced condition, and a marked contrast obtained between the appearances of the gall-bladders according as the gall-stones introduced experimentally into them contained radium or not. Whether containing radium or not, there was a great thickening of the connective tissue of the gall-bladder, and this Dr. Lazarus-Barlow ascribed to the mere presence of the gall-stone as a foreign body. But a fundamental difference obtained in the behaviour of the columnar epithelium lining the gall-bladder according as the calculus which it contained were radium-free or impregnated with radium. If the calculus were radium-free the most that occurred was a slight polypose overgrowth of the epithelium with an excessive formation of mucus; there was no tendency of the epithelium to invade the wall of the gall-bladder. On the other hand, when the lining membrane of the gall-bladder had been exposed to the action of a gall-stone containing radium, the epithelium showed changes indistinguishable from those occurring in columnar-cell carcinoma, in that there was an irregular over-

growth of the epithelium which projected into the cavity of the gall-bladder and invaded the thickened wall of the viscus in an irregular manner. As a consequence of the invasion, parts of the thickened gall-bladder wall showed the presence of irregular tubules lined with columnar epithelium, grouped in irregular fashion, through a less or greater thickness of the gall-bladder wall, and usually preceded by a zone of lymphocytes. In one rabbit a metastatic focus exactly recalling the appearances in the gall-bladder itself was found in a distant part of the liver. This was the sole metastasis found in the entire series of experiments which involved 122 rats, 6 radium gall-stone rabbits, and 3 control rabbits. Reference was made to experiments on the same lines carried out on mice at an early period of the research. In these animals the radium was not contained within tubes, and though introduced beneath the skin in the axillary region in the form of an insoluble sulphate or silicate, was found to disappear from the body within a few weeks. In addition, it was not found easy to keep the animals alive for a prolonged period. Nevertheless, of 67 radium mice living six months after inoculation 5 developed definite malignant tumours of the mamma (one animal bearing two primary tumours) and 7 other animals developed doubtful tumours (1 papilloma and 6 nodular masses, chiefly in the neck, as large as peas, oscillating in size and finally disappearing). Thirteen control animals inoculated the same way but without radium and also living six months after inoculation showed no tumour formation whatever.—Professor S. G. SHATTOCK, whilst fully recognising the value of Dr. Lazarus-Barlow's results, and the prospect they opened up of further developments in experimentation upon the etiology of carcinoma, did not consider that the lesions could safely be regarded as more than pre-cancerous. The downgrowth of the epidermis in the rat's skin in no case transgressed the limits of the corium; and on the removal of the radium the changes, instead of progressing, disappeared. In regard to the proliferative changes set up in the mucosa of the gall-bladder by the action of radium introduced into gall-stones, those seen in the bile-ducts in coccidiosis of the rabbit's liver were quite as pronounced. The speaker held that for the production of carcinoma there still remained a second factor which needed discovery. Dr. Lazarus-Barlow's view that this consisted in a lessened resistance required scientific demonstration; nor was it logically the only other possibility, for there might be a second *extraneous* factor, such as the access of an ultramicroscopic virus. A further point against the change in the gall-bladder being carcinomatous was the circumstance (as Dr. Lazarus-Barlow stated in answer) that the epithelial cells did not yield the proper Altmann granule test. Amongst Dr. Lazarus-Barlow's results there was one in which a metastasis had occurred in the liver; but here a second extraneous factor might have come into play, and the inflammatory proliferative process have been followed by the growth of a proper carcinoma.

Professor SHATTOCK read a paper on Explosive Phenomena in Gunshot Injuries. He observed that from the strictly pathological standpoint the new factor introduced into gunshot injuries, as injuries, was the velocity of the penetrating body; they were otherwise contused and infected wounds like those produced by other foreign bodies, although their number and variety gave them special surgical features. Under the term "explosive effect" more than one thing was included: it was applied (1) to the increase of damage due to shattering of the bullet; (2) to the additional injury resulting from the comminution of a bone and the dispersal of its fragments; and (3) to the damage resulting from the high velocity of the missile, the last alone possessed any special pathological interest. It had been asserted (Professor Dr. K. Stargardt) that the British bullet was an expanding one in consequence of the core being composed of aluminium at the point and elsewhere of lead; that on striking (bone at least) the momentum of the lead carried this forwards over the harder aluminium, and so split the mantle. In order to test this, the author had had recourse to the following experiment. The bullet was fired at a distance of 20 feet through a sterna to cotton-waste, from which it was recovered without having struck any second object. The sternum was ed in order to obtain a direct hit. The bulle found to have undergone no distortion whatever sterna were then spliced together and shot through in t e way; the bullet on recovery was found quite and . In solid organs the results of high velocity were best seen in the liver when perforated by rifle bullets at close range. The typical injury was a perforation accompanied with radial fissuring of wide extent. Even here the elimination of extraneous factors, such as obliquity of impact or turning of the missile in transit, damage due to the introduction of clothing, could only be effected by experiment. In firing through suspended sheep livers at 20 feet with a service rifle and pointed bullet this was the form the injury took; the mechanical action of gas produced by explosion was eliminated by the distance. In analysing the physics of this result the wave of compressed air produced by the bullet (demonstrated by Professor Vernon Boys in instantaneous photography) was wholly negligible. The speaker had found that if tense screens of tissue paper were shot through at 20 feet with a service rifle, the hole was but little larger than the bullet; were the air wave of any moment the paper would obviously have been widely rent. Sir Victor Horsley in commenting upon the cavitation produced in his experiments of firing into clay, attributed more importance to the spin of the bullet (centrifugal action) than to its forward movement. The speaker had carefully inspected all the plaster-casts made from the clay in these experiments, and was unable to find the evidence of such rotation; the coarser ridges (representing shallow fissures in the clay), as well as the finer markings, were longitudinal. The turn of the present British bullet was once in 10 inches; yet explosive effects were observable in, e.g., the sheep livers before referred to, where the thickness was only 1½ inches, which would reduce the rotation to less than one-fifth. In only one specimen in the collection on view in the Royal College of Surgeons of England were the divergent fissures curved; here the bullet had traversed the body of the third lumbar vertebra first, and must have had some altogether exceptional twist imparted to it. The question was thus reduced to one of forward velocity. This was well shown in the liver by the fact that in perforations caused by shell fragments at low velocity a patulous tunnel alone resulted. The same difference was beautifully demonstrated in Horsley's casts, where the distal half was only of the calibre of the bullet, the explosive or dilating effect being limited to the proximal. In the case of the clay, the ready entrance of air from behind allowed of its cavitation; in the liver, where this was out of the question, the cavitation was represented by radial fissuring produced by the passage of the wave through an incompressible semi-solid medium. In *hollow organs* the production of explosive effects depended upon their contents, other things being equal. Such effects from rifle bullets were not observed in the stomach or intestines by reason of the compressible air and gas which they contained, nor in the lung for the same reason. The contusion, unattended with breach of surface, found not rarely in such organs was possible from their extreme mobility and compressibility. The longitudinal wounds produced at times in the intestine by intact bullets were explained by the wall having been struck axially. In the case of the bladder, the contents of which were incompressible, explosive results were now and then encountered. In the collection there was a bladder perforated by a rifle bullet which entered through the buttock without fracturing bone, and eventually escaped above the pubes; in the posterior wall of the bladder was an entry admitting the finger; the anterior wall (exit) was rent from top to bottom. The speaker had obtained similar explosive results by firing through ox bladders distended with water, a service rifle being used at 20 feet. The result was a simple hydrodynamic one and due to the wave imparted to the mobile and incompressible fluid in a confined space. If the bladder was empty or only lightly filled the rending on the far side did not take place. In arteries and veins no hydrodynamic effect was observable, whether in unilateral or bilateral perforation. Its absence was possibly due to the indefinite continuity of fluid above and below the stricken spot, and to the remarkable strength of both kinds of vessels. The speaker had been unable to produce either macroscopic or microscopic damage of the inner or middle coats of the human common iliac artery under the highest water pressure that could be exerted with a dissecting-room syringe. In regard to the skeleton, the rigidity of the structure concerned was a complicating factor. If the upper part of the shaft of the tibia was compressed over a small area in a vice, however *slowly* the compression was made, extensive comminution and fissuring ensued far beyond the spot com-

pressed. Nevertheless, the same rule held: the greater the velocity of the missile the greater the damage. The classical example of explosive effect was the well-known and widespread comminution of the skull when bilaterally perforated by a rifle bullet at close range. The effects due to the gas of explosion had, of course, to be excluded. The results of suicidal shooting were thus liable to lead to fallacious conclusions; a rifle fired into the mouth with blank cartridge would produce extensive comminution. This factor was, however, easily excluded; the speaker, too, had found that sheep skulls with the brain *in situ* underwent extensive comminution when shot through at 20 feet with a service rifle, the foramen magnum being freely open. The result was not, properly speaking, hydraulic but hydrodynamic—i.e., it was not due to a generalised and equable internal pressure, but to the sudden impact of the incompressible cerebral substance against the interior of the cranium. A simple experiment, devised by the speaker, would emphasise this. A large flat-sided "cocoa-tin" was shot through in the empty state, at 20 feet, with a service rifle; a circular entry and exit of about the diameter of the bullet resulted. A second tin was filled with water and similarly shot through, the *lid being removed*. The entry was small and circular; the exit widely split, with large triangular flaps of the metal completely everted. The speaker had obtained pronounced explosive effects also in sheep skulls inverted and filled with water, *the foramen magnum being freely open*. If the skull was shot through in the empty condition a circular entry and exit alone resulted.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Dec. 7th, Dr. A. BROWN KELLY, the President, being in the chair.

The PRESIDENT showed a "Teratoid Growth or Hairy Polypus of the Nasopharynx." The specimen was a long, tongue-shaped growth which protruded frequently from the mouth of a female infant. The growth was first noticed when the baby was a week old, and was removed when the child was six weeks of age. It was attached to the left side of the nasopharynx by a fine pedicle. It could be drawn out of the mouth so as to protrude three-quarters of an inch beyond the lips. After removal it was found to measure two inches in length and half an inch across at its widest part. It was of fleshy consistence and was covered with skin furnished with numerous fine hairs. The central portion of the polypus consisted of tissue closely resembling fat.

The PRESIDENT also exhibited a collection of Dental Cysts and Cysts of the Floor of the Nose. He pointed out that dental cysts which invaded the antrum had been regarded erroneously as "hydrops antri Highmori," or "distension of the maxillary sinus by fluids or mucous cysts." Whereas the cysts really arose outside the antrum, and only pushed their way in as they grew larger. Dental cysts may also, he said, produce a bulging of the floor of the nose, and by extending upwards raise the ala. They must be differentiated from cysts of the floor of the nose, which were retention cysts and presumably arose from long ducts present in this situation.—Mr. H. TILLEY said that, in his experience, cysts of the floor of the nose were always associated with carious teeth and the fluid inside contained cholesterin crystals. He would like to know if the retention cysts mentioned also contained cholesterin crystals.—The PRESIDENT, in reply, stated that he was sure the retention cysts were not connected with the teeth. He did not know if cholesterin was present in the fluid.

Dr. WILLIAM HILL exhibited a patient whose pharyngeal pouch had been treated by a novel method. The man, aged 43, complained of dysphagia, regurgitation of food and gurgling for six months. The existence of a pouch was demonstrated by endoscopic and X ray examination. At the operation the pouch, which was bound to the gullet by fascia, was dissected free, and then the fundus of the unopened pouch was sewn to the left side of the inferior constrictor muscle. A ligature was placed round the neck of the sac in order to prevent food entering, but not tight enough to cause strangulation. For the time being, all symptoms had disappeared. He claimed that the operation was not difficult to perform. There was little risk to the patient, and if at a later date excision of the sac became desirable the operation would be in the neck and not in the mediastinum.—Mr. E. D. D. DAVIS said that Mosher had operated by cutting away the septum between the gullet and the pouch by endoscopic methods. It was therefore desirable to know how firmly the pouch was bound to the side of the gullet. He knew of a case in which Major Waggett had invaginated the pouch, but later, after a violent sneeze, the pouch reappeared. He also knew of a case in which after excision the sac formed again.—Sir STCLAIR THOMSON also knew of a case in which there was recurrence after removal of the sac.—Dr. DUNDAS GRANT thought that when the sac was long Mosher's operation would not be successful. In his opinion dilatation of the upper end of the œsophagus should be practised after operation in order to prevent recurrence.

Cases and specimens were also shown by Dr. GRANT, Mr. TILLEY, Mr. HUNTER TOD, Sir STCLAIR THOMSON, Dr. W. JOBSON HORNE, Dr. W. H. KELSON, Mr. NORMAN PATTERSON, Dr. W. H. JEWELL, Dr. IRWIN MOORE, Mr. GEORGE C. CATHCART, and Dr. DAN MCKENZIE.

SECTION OF ELECTRO-THERAPEUTICS.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this section was held on Nov. 16th, Dr. G. HARRISON ORTON, the President, being in the chair.

Dr. E. P. CUMBERBATCH showed a girl in whom a Nævus of the Nose and Air Sinuses had been successfully treated by means of X rays. At the age of 5 she developed a nævus on the nose, and had as a symptom hæmorrhage. The neoplasm extended into the nasal chambers, the antrum, and nasal sinuses. At times the bleeding was very copious. At times arteries were tied, but occasional profuse hæmorrhages still occurred; even ligature of the external carotid did not check them. As she came to the hospital blanched, and there was nothing left to tie, she was brought to the X ray department. Treatment here was commenced in November, 1911, and was carried out tri-weekly. There was not much diminution until January, 1912; in March and April there was no hæmorrhage. The treatment was continued until the middle of the year. Later in 1912 she had another severe attack, and resumption of the rays brought about diminished bleeding at rarer intervals. She remained fairly free until August, 1914, when a severe hæmorrhage occurred from an artery on the nasal septum. Treatment of this was by the diathermic cautery, and no further bleeding occurred for three years, until a slight attack a fortnight ago. He asked for views as to whether the diminution of the bleeding could be directly attributed to the X rays. In the first treatments she had a Sabouraud dose unfiltered at 3-weekly intervals; in the second series a half Sabouraud dose filtered through $\frac{1}{2}$ mm. of aluminium.

Dr. REGINALD MORTON said he had not treated nævus with X rays; for these he had managed with either electrolysis, the cautery, or CO_3 snow. But he had not encountered a nævus invading the nasal sinuses. The result in this case seemed encouraging. It was doubtful whether the dosage given in this case sufficed to produce endarteritis obliterans and so cause shrinkage of such a growth. The blood-vessels of a nævus were not so richly lined with endothelium as were normal vessels.

Dr. F. HERNAMAN-JOHNSON said he had treated such cases with small doses of rays two or three times weekly for six or eight weeks, and then left the condition alone. But none of the cases were hæmorrhagic.

Dr. MORTON showed skiagrams of a remarkable case of Hair-ball in the Stomach. The case, that of a woman under the care of Dr. Robert Hutchison, was one of gastric disorder of a very puzzling nature. She could not take more than 6 or 7 ounces of food at a meal, and the whole of it remained in the fundus, and the lower level of an opaque meal, instead of being cup-shaped, was horizontal. It became obvious that the trouble was due to the presence of a hair-ball. This was removed and was found to weigh 3 lb; its length was 12 in. and its greatest circumference 9½ in. As a schoolgirl the patient had been in the habit of pulling out single strands of her hair and swallowing them. The specimen is in the Museum of the Royal College of Surgeons of England.

Dr. A. C. JORDAN read a contribution on a method of control of the Coolidge tube.

Among the appliances exhibited was one by Dr. ALASTAIR MACGREGOR, adapted from a French invention, in which water was used as the rheostat, for producing a slow or quick rise and fall of galvanic current from zero to maximum, in either direction.

Reviews and Notices of Books.

A Manual of Pharmacology and its Applications to Therapeutics and Toxicology. By TORALD SOLLMANN, M.D., Professor of Pharmacology and Materia Medica in the School of Medicine in the Western Reserve University, Cleveland, U.S.A. With 29 figures in the text. London and Philadelphia: W. B. Saunders Company. 1917. Pp. 901. Price 20*s.* net.

THE revision of the United States Pharmacopœia has apparently induced Professor Sollmann to issue a new edition of his well-known text-book, or rather, it might be said, to write a new one, for the changes are so many and the outlook in therapeutics so different since the first edition appeared in 1901 that it cannot be regarded as a mere revision. As is stated in the preface, the book has two objects: first, to convey the broad conceptions and generalisations which are necessary for the everyday work of the student and practitioner and which must be assimilated in undergraduate days; secondly, to serve as a book of reference in regard to questions which may present themselves at any time in the use of drugs, and in the instruction of more advanced students. With these objects in view, the manual is printed in two types, the larger subserving the first of giving a general view while the smaller type deals with less essential details. Opinions may differ as to the appropriate allocation of some paragraphs, some of those printed in small type might be dignified with the larger, and vice versa, but, on the whole, the compromise seems satisfactory. In the smaller type the recent literature is succinctly dealt with; we wish that Professor Sollmann had more often expressed his own views in regard to contradictory statements cited; his wide experience in experimental work would often aid in determining contested questions where ordinary readers may have difficulty from their unfamiliarity with the original papers and their ignorance of the capacities of the conflicting writers.

The arrangement of the chapters in a text-book of pharmacology presents great difficulties and has not been entirely successful in any hands so far. Professor Sollmann states that he follows in the main the classification introduced by Buchheim, and as far as the grouping of very closely related bodies—for example, the atropine class—he agrees with that adopted by all the better text-books of the day. But we have failed to understand on what principle the larger arrangement is based. Has the author given it up in despair? For example why should phlorhizin be placed in the midst of the animal extracts and why is the discussion of anaphylaxis inserted between the paragraph on viburnum and the chapter on nitrites?

On some minor points we would join issue with the author. He seems to doubt the identity of yohimbine with quebrachine, though this was established by Fourneau's researches, for he appends the former rather notorious alkaloid to the cocaine group and makes no reference to it under aspidosperma. It may be doubted whether chloroform or morphine causes the appearance of glycuronic acid in the urine, but the juxtaposition of these drugs with chloral and camphor (p. 477) suggests that the evidence is equally valid for all four. Professor Sollmann still encourages the use of alkali carbonates along with the salicylates, although this is deprecated by most authorities who have worked on the subject. On p. 551, the concentration of alcohol in the blood of drunkards is stated to be sometimes as much as 2½ per cent., an impossible number; it is obviously a misprint for 2½ per mille.

These are, however, trivial blemishes; the Manual is a most successful presentation of the present knowledge of the action of drugs in health and disease, and is a mine of information from which both student and practitioner may draw with benefit and with confidence. We can cordially recommend it to their attention, and wish it a wide circulation in this country as well as in the United States. One feature that will prove of special value to workers on therapeutics in this country is the full treatment of the valuable work done by many clinical and experimental investigators under the American Medical Association and independently. These papers are sometimes difficult to obtain on this side of the Atlantic but they have justice done them by the author. The more important preparations of the United States and the British pharmacopœias are discussed, and some of those of the various pharmaceutical commentaries. A very useful bibliography extending to nearly 60 pages is appended. The directions for practical laboratory work for students, which formed a feature of the first edition, is omitted in this one, but is promised in the form of a separate volume.

Malingering and Feigned Sickness, with Notes on the Workmen's Compensation Act, 1906, and Compensation for Injury, including the Leading Cases Thereon. By Sir JOHN COLLIE, M.D Aberd., J.P., Physician, Hospital for Epilepsy and Paralysis, Maida Vale; Honorary and Temporary Lieutenant-Colonel, R.A.M.C., &c. Illustrated. Second edition, revised and enlarged. 1917. London: Edward Arnold. Pp. 680. Price 16*s.* net.

THE first edition of Sir John Collie's useful and practical work on "Feigned Sickness" was published in 1913, and he mentions in his preface to the second that "much of the leisure time of four years has been spent in amplifying and bringing it up to date."

The war is naturally responsible for a new chapter on "Military Malingering," but the additions deal chiefly with phases of the main subject more closely connected with industrial and social conditions in normal times. Chapters have been added upon self-inflicted injuries, upon malingering in connexion with skin affections, miner's nystagmus glycosuria and incontinence of urine, upon the Workmen's Compensation Act, 1906, and scheduled diseases, "return to work," the effect of recent legislation upon sickness and accident claims, suppuration and its prevention, immobility after joint injury, rheumatism and fibrositis and their relationship to accident, and upon the ligaments and muscles of the back. Many illustrations have also been added. The quite valuable chapter upon "Return to Work" explains and discusses the drawbacks which accompany the advantages attending the invitation issued frequently by employers to injured workmen to resume their duties on full wages which, in fact, they are not capable of earning. The author's observations on the policy of workmen's compensation and its administration are well worth the consideration of employed, employers, and their legal advisers.

Sir John Collie seems to be as well conversant with the legal as with the medical side of his subject. We may call special attention to the chapter on the conduct and position of medical witnesses, which will be found among those towards the end of the volume which deal with more or less legal matters, for it contains information which anyone expecting to be called as a medical witness might read with advantage. We have here a brief summary of the question of such a witness's privilege, together with sound advice upon the manner in which the witness should prepare for his task and comport himself when fulfilling it. Some of the author's maxims upon conduct in the witness-box are amusingly precise, but his instruction to "Watch the judge's pen" would have had to be qualified a few years ago by the exception "unless it be Sir Fitz James Stephen," for that distinguished but sometimes rather peremptory judge used to declare himself disconcerted by a witness who timed his replies by observing when his lordship's notes were completed. There may be others even now whose nerves are similarly affected, though they be less emphatic in their admission of their peculiarity. That a witness should be "exact, lucid, and succinct" is, of course, desirable, whether he be a medical man or not, and Sir John Collie's writing forms a good example of these virtues. The second edition of his work amplifies the information in the first, and deals satisfactorily with a subject of growing importance and with a large literature accumulating round it. It can safely be recommended to medical men concerned with the examination of persons whose interest it is to feign or to exaggerate symptoms of disease, and we may add the hope that it will not be introduced too liberally into those free libraries in which, it is said, the malingerer is able to train himself to play his part.

Insanity in Everyday Practice By E. G. YOUNGER, M.D Brux., M.R.C.P. Lond. Fourth edition. London: Baillière, Tindall, and Cox 1917 Pp. 134. Price 5*s* net.

IN this new edition Dr. Younger has added brief notes on neurasthenia as seen during the present war, and on the modern cult of psycho-analysis. The latter, whatever its psychological interest, he finds unlikely to be of assistance in cases of insanity met with in general practice.

The Treatment of Diabetes Mellitus. With Observations upon the Disease based upon Thirteen Hundred Cases. By ELLIOTT P. JOSLIN, M.D. Harv., M.A. Yale, Assistant Professor of Medicine, Harvard Medical School, &c. Second edition, enlarged and thoroughly revised. Illustrated. Philadelphia and New York: Lea and Febiger. 1917. Pp. 559. Price $4.50.

IN recent years the study of metabolism has been vigorously prosecuted in the United States of America, and the research work that has been done there has contributed largely to our present knowledge of the subject. Among other problems that have attracted attention and been attacked with a considerable degree of success are those relating to the disturbances in the chemistry of the body met with in diabetes mellitus. Although the essential causes of the condition are as yet obscure, sufficient new information has been obtained radically to alter many of our previous conceptions of the disease and its complications, with resulting changes in their treatment. This state of things has been contributed to by a number of observers, most of whom have been enabled to carry on their work through the far-sighted generosity of wealthy Americans who have founded laboratories where research can be carried on under ideal conditions of endowment and equipment, but the improvement in the immediate outlook of patients suffering from diabetes is largely owing to the painstaking researches of Dr. F. M. Allen, of the Rockefeller Institute of Medical Research, who demonstrated first on animals and subsequently on man the increase in carbohydrate tolerance that may be brought about by prolonged fasting and regulated physical exercise in the diabetic condition. Since Allen published his results in 1913 a number of text-books dealing with this method of treating diabetes have appeared, but in none of them has it been so thoroughly and authoritatively dealt with as in that written by Dr. E. P. Joslin, assistant professor of medicine at Harvard. The first edition of Dr. Joslin's book, appearing in 1916, was quickly exhausted, and is now followed by a second, which has been enlarged and largely rewritten. In the additional 120 pages or more of the new edition questions raised by doctors and patients since the previous publication are dealt with, and a large amount of fresh material has been introduced. The further experience gained in the treatment of 300 additional cases has been made use of and enabled the author to give a more definite description of the treatment he finds most successful, besides showing in what respects it has been found advisable to deviate from the plan, based upon Allen's original experiments, previously followed.

The most notable innovations in this edition are the new teaching with regard to the treatment of acid intoxication and the limitation of the initial fasting period. Dr. Joslin now condems the use of sodium bicarbonate to combat acidosis, holding that the dangers attendant upon the employment of this or any other alkali far outweigh their advantages even in impending coma. Instead he would prevent the development of acid poisoning by controlling the fat in the diet from which the acid bodies are mainly derived; this he considers is safer, easier, and more agreeable for the patient. As it is not the fat itself that is harmful but the suddenness with which the ratio of fat to carbohydrate in the diet is changed, any alteration must be gradual, bearing in mind that an excess of carbohydrate is often less harmful to a diabetic than fat with little or no carbohydrate to promote its utilisation. In order to prevent the appearance of acidosis during fasting, and to control it when present, great care is advised in preparing the patient for the withdrawal of food. As a first step fats should be omitted from the ordinary diet; a couple of days later the proteins are dropped; next the carbohydrate is halved until only 10 grammes are being taken, and not until then is the fast commenced. When the urine has been rendered sugar-free the precautions against acid poisoning are continued by increasing the diet in the reverse order, commencing with carbohydrates, passing to proteins, and finally adding fat, to which the patient must be gradually accustomed, for "although fat forms the chief constituent of a diabetic's diet he must not be poisoned with it." Considerable stress is laid, too, upon the importance of a sufficient quantity of liquid being taken, especially liquids containing salts, such as broths and mineral waters, by patients during the fasting period and when acid intoxication assumes threatening proportions. Dr. Joslin maintains that the exclusion of salt from the diet of a severe diabetic hastens coma and that occasionally a case of coma may be rescued by the free use of salt. Since these principles have been adopted the proportion of deaths from coma has fallen from 64 per cent. for the 18 years ending Dec. 18th, 1915, to 44 per cent. for the year 1916. It is important to note, however, that a new cause of death has made its appearance in Dr. Joslin's statistics, three patients having succumbed to inanition. It is probably in part owing to this that he has discontinued the long fasts, originally advised by Allen, that are occasionally necessary to free the urine from sugar at the first trial, and now limits the initial fast to four days. If glycosuria persists at the end of that time a system of intermittent fasting is employed, periods of abstinence from food of diminishing length being interspersed between periods when a limited diet is allowed. It is stated that with this plan no uncomplicated case has failed to become sugar-free and the expectation of life has been prolonged. Formerly the first year after the discovery of diabetes proved to be the most dangerous, 68 per cent. of deaths occurring in that period, but now the mortality has fallen to 17 per cent. for the first year, and the second has come to be the most dangerous.

In his enthusiasm for a new method Dr. Joslin does not forget that in the past good results were obtained with the majority of diabetics without systematic fasting, and that gradual restriction of the carbohydrate intake was the means generally employed. When this is combined with careful limitation of the protein and fat allowance even better results are secured and actual fasting often becomes unnecessary. It is chiefly in the management of long-standing, complicated, obese, elderly, and severe cases that he finds Allen's method has simplified the treatment and proved of greatest service, but even here it must be used with discretion and understanding. Fasting resembles in its action the drugs morphine and digitalis; they frequently give surprisingly good results even when carelessly employed, but they often do harm, and their true worth can only be recognised when they are prescribed with intelligence. It should always be borne in mind that when a patient's strength has been diminished by fasting an incorrectly balanced diet will sooner or later cause a return of the glycosuria with increasing acidosis, and that the last stage of the case will then be worse than the first. It is comparatively easy to get the urine of a diabetic free from sugar, but to keep him so, and in good health, is much more difficult. The determination of the carbohydrate tolerance is only a small part of the problem; the fats and proteins must also be given in proper amounts, and the patient must be educated to carry out his diet with understanding, while appropriate changes in the food allowance must be made from time to time to meet changing circumstances. The sooner the treatment is started the more thoroughly it is carried out; and the more completely the patient understands the principles on which it is based the better will be the results. So impressed is Dr. Joslin with the importance of early diagnosis that he would advise everyone to have the urine examined at least once a year on some fixed day, such as a birthday.

It is claimed that one of the great advantages of the fasting treatment is its simplicity, complicated analyses of the urine, blood, &c., being rendered unnecessary, and we have it on Dr. Joslin's own authority that he keeps his laboratory records on slips six and a quarter by one and one-sixth inches, "so as not to impress the patients with awe." In mild cases simple qualitative and quantitative methods are no doubt sufficient to allow of satisfactory regulation of the treatment, but we cannot agree that it is true in severe cases where secondary disturbances of metabolism have occurred and where the utilisation of protein and fat, as well as carbohydrate, is seriously at fault. The problem is then too complicated to be solved by the imperfect data afforded by such analyses or by any rule-of-thumb procedure. The interests of the patient demand that all the information to be secured by a complete investigation of his defective metabolism by every method known to modern science should be employed and to withhold even part, simply because it involves a considerable amount of laborious work, cannot be good treatment, although it may make it easier for the physician. It is possibly owing to the fact that Dr. Joslin considers more than simple methods of analysis of the urine now unnecessary that the section of his book dealing

with the chemistry of the urine is the least satisfactory part of it. To mention only one example, we should have thought that, even in a book entitled "The Treatment of Diabetes Mellitus," a more adequate account of the reducing substances other than dextrose met with in the urine would have been desirable than is given in the page and a half devoted to the subject, for in addition to the question of differential diagnosis it is surely worth considering whether their presence calls for some particular treatment. It is now generally recognised that analyses of the urine should be controlled by examinations of the blood and respiration as much as possible, and that the aim of our treatment should be not only a sugar-free urine, but also a normal sugar and lipoid content of the blood with a normal carbon dioxide tension of the alveolar air. A thorough account of the modern methods employed in these estimations is given by Dr. Joslin, who devotes nearly 40 pages to their consideration. He emphasises the importance of exercise in reducing hyperglycæmia, and points out that Allen has shown that a single fast-day with exercise may reduce the blood-sugar as much as several fast-days without exercise, while his clinical experience indicates that patients retain their strength and appearance better during fasting when moderate exercise is taken than when they are allowed to remain in bed.

In agreement with most modern writers on diabetes Dr. Joslin is averse from the routine employment of drugs, especially those that are supposed to control the excretion of sugar, and states that in his experience those who use drugs most examine the urine quantitatively the least. The administration of medicines to control the glycosuria can only be regarded as a confession that a proper diet has not been prescribed and that the confidence of the patient has not been secured. His rule is to wait at least a year before prescribing any drug. Since diet is the keystone of treatment, it is necessary that every physician who undertakes the care of a case of diabetes should make himself thoroughly acquainted with the composition of the food materials that are commonly used. For that purpose the information and tables given in this book will be found of great service, for they include the standard analyses of American foods compiled by Atwater and Bryant and also figures abstracted from the special reports on so-called diabetic foods made by Street for the agricultural experiment station of New Haven. With regard to these analyses of "diabetic" foods it should be noted that although some of them contain only a very small percentage of carbohydrate their protein content is almost invariably high and that they are therefore capable of furnishing a large amount of sugar. Failure to recognise this fact, and the fraudulent character of many of the most widely advertised bread substitutes have been two of the commonest causes of failure in the treatment of many cases of diabetes in the past. Their use should be discouraged, at any rate at the beginning of treatment, and if they are allowed later they should be employed for one, or both, of two definite purposes: (1) As an aid in determining carbohydrate tolerance; (2) when the tolerance has been learnt, as a food containing a reduced amount of carbohydrate. In either case it is essential that their exact composition should be known and that they should not be prescribed indiscriminately but in definite amounts. Dr. Joslin considers that no patient should be allowed to become dependent upon special diabetic foods; they are expensive, are sometimes unobtainable, always make him conspicuous, and may eventually become so nauseous that it is difficult to adhere to a diet containing them. One of the great merits of modern methods of treating diabetes is that the use of special foods is unnecessary, for by a quantitative regulation of the diet such as is now generally employed most diabetics are able to take ordinary foodstuffs in sufficient amounts to meet their requirements and yet avoid glycosuria. The untreated diabetic is a food spendthrift, and, according to Dr. Joslin, the food he wastes in a week may be sufficient to feed a soldier for a year, a matter of no small importance at the present time. The prevention of this waste is largely in the hands of the medical profession, as the elimination of unutilised sugar in the urine by most diabetics can be avoided by early diagnosis, prompt treatment, and suitable education of the patient.

To those who wish to make themselves familiar with Allen's method, so as to give their patients the benefit of the most recent developments, we can thoroughly recommend this book, which is dedicated to the "Medical Profession of the United States of America and her Allies, upon whom devolves the *training* of their million diabetics." It bears the stamp of wide clinical experience, combined with scientific knowledge, and presents in an eminently readable manner a subject full of difficulties and pitfalls for the unwary.

LIBRARY TABLE.

Practical Guide to Diseases of the Throat, Nose, and Ear, for Senior Students and Junior Practitioners. By WILLIAM LAMB, M.D Edin., M.R.C.P. Lond. Fourth edition. London: Baillière, Tindall, and Cox. 1917. Pp. 372. Price 8*s.* 6*d.* net.—This helpful guide to the beginner has been revised and brought up to date for its new issue after three years. The author has contented himself with filling up various small lacunæ without adding materially to the size of the book, which will be found, as before, to fulfil its modest purpose admirably.

Electro-Therapeutics for Military Hospitals. By WILFRID GARTON, M.R.C.S., L.R.C.P. Lond., Temporary Captain, R.A.M.C. London: H. K. Lewis. 1917. Pp. viii. + 48. Price 2*s.* 6*d.* net.—This small monograph consists essentially in a plea for the more general use of electrical applications in the many disabilities brought about in the course of the present war. While the author is right in his contention that electro-therapeutics have not received full employment, there is nevertheless much cause for gratification in the enormous development of the use of these methods since the war began. We have only to visit one of the many general military hospitals, or more particularly one of the several orthopædic hospitals, to see how much electrical treatment is now relied upon to alleviate and cure the results left by wounds and disease. The author tells us nothing that is new to those who specialise in this line of work, but his book will be of help to those who have to carry out electro-therapeutics, especially in military hospitals.

Sanitary Law and Practice: A Handbook for Students of Public Health and Others. By W. ROBERTSON, M.D. Glasg., and CHARLES PORTER, M.D. Edin. Fourth edition. London: The Sanitary Publishing Co., Ltd. 1917. Pp. 750. Price 12*s.* 6*d.* net.—The stasis in health legislation has necessitated little alteration in the text of this handbook since its last appearance five years ago, and 20 pages of appendices suffice for the summary of recent Acts and regulations. The handbook facilitates a study of the heterogeneous mass of conflicting data which constitutes our present sanitary code as far as such help is possible, but we sincerely trust that by the time the next edition is called for the whole precarious edifice may have been bonded together by a Ministry of Health into a single consistent structure. We doubt not that the authors will welcome this addition to their labours.

Easy Italian and How to Pronounce It. By Captain KEYWORTH. Third edition. Hove: Combridges. Price 3*d.*—In this little book Captain Keyworth puts out in conversational form the phrases that would be most useful to the stranger, especially the soldier, who found himself in Italy in circumstances where a little knowledge of the language was made necessary by his circumstances. The questions necessary to find a locality or a route, to obtain food, drink, lodging, or clothing, to obtain a date or reach a hospital or a doctor, are simply set out in English and Italian, and in the latter language they are spelt out phonetically. A few military terms are given, and, to meet the exigencies of the wounded in particular, the Italian terms for the parts of the body are included.

L'Exploration Radiologique des Voies Urinaires. By le Dr. ARCELIN, Chef de Service de Radiologie à l'Hôpital Saint-Joseph et à l'Hôpital Saint-Luc. Paris: Masson et Cie. 1917. Pp. 175. Price 6 francs.—This work is one of special appeal to all those who are more or less directly interested in the X ray examination of the urinary system, comprising as it does all the latest ideas of the French school on this very important subject. The work is so written that it will be of value to the physician and the surgeon as well as to the radiologist, and each will find detailed information on almost any phase of the subject in which he is more particularly interested. The illustrations and diagrams leave nothing to be desired, and a very valuable chapter is devoted to the localisation of projectiles in the vicinity of the urinary organs.

BOOKS FOR NURSES.

OF late years there has been no lack of useful books written to aid nurses during their training and afford means of reference afterwards. Indeed, the choice for the nurse, as for the medical student, is at times bewildering. Among the more ambitious of the books before us is *A Complete System of Nursing* (London: J. M. Dent and Sons. 1917. Pp. 746. Price 10*s*. 6*d*. net), by Miss A. MILLICENT ASHDOWN, examiner in nurses' practical work to Guy's Hospital, who has based her system on that of the late Miss Honnor Morten, while rewriting the text entirely. In this the nurse is instructed how to carry out any and every of her multifarious duties, chapters dealing in succession with medical, surgical, and special nursing. Poisons, diets, weights and measures, and useful tables are given in later sections.—Anatomy and physiology omitted from this work are admirably dealt with by Dr. Percy M. Dawson, assistant professor of physiology at Wisconsin, in *Elements of Anatomy and Physiology for Nurses* (New York: The Macmillan Company. 1917. Pp. 279. Price 7*s*. 6*d*. net), which is well calculated to interest the reader in what too often are regarded as mere lessons.—Two other books published by G. P. Putnam's Sons also deal with subjects preliminary to clinical work: in a *Text-book of Materia Medica for Nurses* (Fourth edition. 1916. Pp. 243.) Miss LAVINIA DOCK deals concisely with the characters of drugs, inorganic and organic, and the main points of their action and uses. In *Physics and Chemistry for Nurses* (1916. Pp. 444 Price 7*s*. 6*d*.) Miss AMY E. POPE, who has already written much for nurses, has collected a large amount of useful information imparted in an interesting manner, but the value of the book as a whole is marred by very unequal treatment.—Dr. H. S. RUTHERFORD DARLING, Assistant Surgeon to the South Sydney Hospital, may be read with profit in his *Surgical Nursing and After-Treatment* (London: J. and A. Churchill. 1917. Pp. 582 Price 8*s*. 6*d*. net) by others than nurses. His book really includes a treatise on minor surgical ailments and the measures required to deal with them. In an *Elementary Hygiene for Nurses* (London: J. and A. Churchill. 1917. Pp 152. Price 3*s*. net) Dr. Darling has succeeded within small compass in giving an excellent and comprehensive sketch of preventive medicine in its various branches, and this work also may be read with profit by medical students and practitioners as well as by the nurses, for whose final examination at the Australian Trained Nurses' Association it was written.—Dr. CHALMERS WATSON, in *Lectures on Medicine: a Handbook for Nurses* (Edinburgh: E. and S. Livingstone. 1917. Pp. 295. Price 4*s*. 6*d*. net), puts in practice his belief of the desirability of grounding nurses more thoroughly in medicine than is usually done. His method of instruction cannot fail to interest.—Dr. J. K. WATSON, in a book written "more especially for nurses and midwives," sets out *The Venereal Diseases Problem* (London: Baillière, Tindall, and Cox. 1917. Pp 54. Price 2*s*. 6*d*. net) in a manner that will conduce towards the needed enlightenment.—Finally, in *A Text-book of War Nursing* (London: G. P. Putnam's Sons. 1917. Pp. 227. Price 3*s*. 6*d*.) Miss VIOLETTA THURSTAN writes from her personal experience of nursing under war conditions in Belgium, Russia, and France, for the help of sisters and nurses working in military hospitals.

JOURNALS.

The Indian Journal of Medical Research. Vol. V., No 1.—This number contains 15 separate articles and extends to 272 pages, along with many plates. Major E. D. W. Greig contributes three papers, in two of which he continues his valuable Bacteriological Studies of Cholera-like Vibrios Isolated from the Stools of Cholera Cases in Calcutta, one paper dealing with morphological and cultural investigations and the other with feeding experiments on rabbits. He thinks that as finer methods of technique are evolved it may be possible to establish further and more definite differences in morphological and cultural characteristics between cholera-like vibrios themselves and between this class and the standard cholera vibrio. From the feeding experiments he found that some strains produce only slight illness, while others cause rapidly fatal results. This observation probably helps to explain the known variation in the severity of epidemics and individual cases of cholera. Major Greig's third paper consists of some observations on the effect of intravenous injections of antimonium tartaratum on malarial parasites. He found that the injection intravenously of this preparation of antimony entirely failed to destroy the malignant tertian crescents or rings; also that the rings and gametes of the benign tertian parasite were unaffected by the antimony.—A joint paper is furnished by Major J. Cunningham, Major H. C. Brown, and Dr. K. R. E. Iyengar, of the Central Research Institute, Kasauli, on the preparation of vaccines on a large scale. Their inquiry was undertaken in view of the greatly increased demand for vaccines of different kinds, both for the armies in the field and for the drafts which are constantly being sent as reinforcements.—Major J. Cunningham, in conjunction with Captain H. H. King, in continuance of previous work on the subject, supplies a description of further investigations on dysentery in the jails of Eastern Bengal, being the report on a special inquiry conducted under the auspices of the Indian Research Fund Association and dealing largely with the bacteriology of dysentery organisms.—The Susceptibility of Indian Milch Cattle to Tuberculosis is the subject of a most interesting paper by Major W. Glen Liston and Dr. M. B. Soparkar, with many illustrations. Their investigations confirm the general experience that Indian cattle are less commonly affected by tuberculosis than English cattle, and support the view that the comparative infrequency of the disease among cattle in India is due to a natural resistance rather than to any method of housing or keeping of cattle in India. Incidentally, the investigations shed some light on the practical absence of tuberculosis caused by the bovine type of bacillus in children and adults in India. This latter part of the subject is to be discussed by the authors in a subsequent communication.—Lieutenant-Colonel W. D. Sutherland, Imperial serologist, Calcutta, writes critically on "the Wassermann reaction as explained by Major Nesfield."—A joint paper by Lieutenant-Colonel J. W. Cornwall and Assistant Surgeon T. Kesava Menon, on the possibility of the transmission of plague by bed-bugs, has already been commented upon in our issue of Dec. 1st.—Mr. P. R. Awati, medical entomologist, Indian Research Fund Association, gives a further instalment of his Studies in Flies, discussing this time the classification of the genus *Musca* and giving a description of the Indian species, with numerous illustrative plates.—Two papers are contributed by Captain J. A. Sinton, the first on a trematode parasite of anopheline mosquitoes and the second on the anopheline mosquitoes of Kohat.—Lieutenant-Colonel Clayton Lane writes on Ankylostoma *Duodenale* as a parasite of *Felis tigris*, and Dr. G. C. Chatterjee, assistant professor of pathology, Calcutta, describes a trichomastix, parasitic in the human intestine. As this has not hitherto been described, he feels justified in regarding it as a new species, to which he gives the name of *Trichomastix hominis*.—*Tricophyton Viannai* (n. sp.), the infecting agent in a case of dermatomycosis, is described by Captain Froilano de Mello, director of the bacteriological laboratory, Nova Goa (Portuguese India), with numerous illustrations. The parasite in question was probably of African origin and was most likely derived from some animal.—The problem of the amœbic dysentery carrier in India and Mesopotamia is discussed by Temporary Captain W. MacAdam, R.A.M.C., and Assistant-Surgeon R. Keelan, I.S.M.D.

Maternity and Child Welfare. Vol. I., No. 11. November. 1917. Price 6*d*. net.—The successful child-welfare worker has a passion for detail of a concrete and practical kind, and this taste is admirably catered for in Miss Grace Owen's "The Nursery School" and in the articles on Infant Welfare Centres, by Dr. Sylvester Richmond and Miss Lilian Seth-Smith. The importance of applying the results of medical research and scientific discovery in public health work is insisted on in this number and both "The Problem of Nursing in Rural Districts," by Mrs Oliver Bellasis, and "A Scheme for the Betterment of Conditions of District Midwifery Practice," by Miss Alice S. Gregory, illustrate the practical difficulties of the task. If the public, especially the poorer section, is to have the full benefit of the results of medical research, skilled nursing for all in illness and for women in childbirth is indispensable; the ignorant and unskilled cannot carry out doctors' orders. Similarly, constructive and preventive work, such as town-planning, health visiting infant-welfare work are hampered because the connecting link is too often lacking—the link which would serve to coördinate the various efforts and keep them all in touch with enlightened scientific thought. Of course, this all points one way, to the need for the central authority which would coördinate separated effort.

Recurrent Fever
SYPHILIS

GALYL

Framboesia
Sleeping Sickness

3000 Injections (intravenous) were given in one of our **Service Hospitals.**

"No case has given the slightest cause for anxiety, and the clinical results are very satisfactory."
Staff Surgeon's Report.

GALYL is as effective as SALVARSAN or NEOSALVARSAN on Spirochætes and Trypanosomes, more rapid in action, and free from the neurotropic and congestive action of these preparations.

FOR INTRAVENOUS INJECTIONS:—
(1) **DILUTE.**—GALYL is supplied in neutral glass ampoules containing the necessary dose of Sodium Carbonate, sterile distilled water only being used for the dissolution.

(2) **CONCENTRATED.**—A special outfit containing one dose GALYL, one ampoule sterilised solution, and one small filter is supplied.
DOSES.
0·10—0·15—0·20—0·25—0·30—0·35—0·40.

(3) FOR INTRAMUSCULAR INJECTIONS:—
GALYL is supplied in **GLUCOSE SOLUTION.**
DOSES.
0·10—0·15—0·20—0·30—0·40.

THE IMPROVED INTRAMUSCULAR INJECTION.

A STABLE SOLUTION *NOT* an Emulsion.

The GALYL is in the form of a Sodium Salt in a weak solution of Glucose. This is much easier to use and more rapidly absorbed than the oily emulsion. It is in every way identical with the intravenous — efficacy, dose, price, &c., only differing in administration.

Thorough and exhaustive tests in various parts of the Kingdom have proved it to be equal in every way with the intravenous; moreover, patients may resume and continue their occupations without inconvenience after injection of Intramuscular GALYL.

LATAPIE
SERO-REACTION FOR SYPHILIS

Simplified Wassermann Test of the Pasteur Institute.

The Latapie process, which only requires **three** test-tubes, has marked advantages over other methods; it simplifies the technique and makes errors almost impossible.

This statement is based upon extensive practical experience embracing more than 100,000 examinations conducted at the Pasteur Institute with blood collected at the Institute itself or sent in from outside sources.

Accurate—Reliable—Uncomplicated—Economical.

The Antigen is supplied in tubes, which is diluted 22-26 times (according to indications on each tube).

It keeps good and fully active for several years if kept at room temperature and protected from light.

Full and Complete Instructions with each Tube.

Further Literature sent on Application to Medical Practitioners and Pharmaceutical Chemists by the Sole Agents for the British Empire—

27

The TREATMENT of CARBUNCLES, BOILS, ANTHRAX, ACNE, STYES, and Diseases arising from Staphylococcus.

STANNOXYL

(An Oxide of Tin and Tin Metal Free from Lead).

A scientific production the value of which has been studied very closely. The effect is very prompt; from the second day of treatment the pain is relieved, the carbuncles begin to dry up, and those which are just opening are stopped in their course; the core is not expelled but reabsorbed.

In the majority of cases definite results are obtained within five or six days; it is seldom necessary to take the full ten days' treatment, and relapses are unknown.

The daily dose for adults is 4 to 8 tablets; children 2 to 4 tablets.

Supplied in vials of 80 tablets.

The SCIENTIFIC TREATMENT of INFLUENZA and Allied Ailments.

KINECTINE

According to Dr. MOUNEYRAT, the discoverer of Galyl (the widely adopted Salvarsan Substitute).

FORMULA:—Chlorhydrate of Quinine c. Hectine—i.e., *Benzo-sulfone-para-amino-phenyl-arsenate of Quinine.*

Non-toxic, produces no ill results. Easily taken (tablets) and well tolerated.

Highly satisfactory clinical results.

Not only a prophylactic against, but a specific in, **INFLUENZA, Catarrh, Coryza, NEURALGIA, Malaria, &c.**

H.M.S.———, 27-7-17.

SIR,—I enclose P.O. for the tube of Kinectine. The drug has given every satisfaction.
The Anglo-French Drug Co., Ltd., Holborn, London, E.C. W. B. H. W., Surgeon, R.N.

RATIONAL TREATMENT of CONSTIPATION By the double action of secretions and peristalsis.

OPOLAXYL

Opolaxyl is a combination of the secretions of the liver (biliary), pancreas, and intestines, with vegetable extract of a non-drastic nature.

It combines all the secretions to correspond to nature's therapy and promotes a flow of bile and glycogen with their hæmatopoietic and antitoxic properties.

It is a normal regulator of the gastro-intestinal functions; consequently it improves the metabolic exchanges in the entire organism.

Opolaxyl does not lose its efficacy by prolonged use; its effect is gentle and constant, without irritation. It is not merely purgative; it stimulates the defective organs and revives the normal equilibrium; it has a lasting effect because it restores the organs, thus correcting diminutional function.

Opolaxyl is put up in small size tabular form easy to swallow, and should be swallowed without crunching at bedtime or before breakfast.

DOSE—For obstinate constipation 2 or 3 tablets, afterwards 1 tablet every 3 or 4 days for a month.

E———, Scotland, 9th Oct., 1917.

DEAR SIRS,—Having derived considerable benefit from the use of Opolaxyl tablets in my own personal case, I write as a practising physician to ask if you would make any reduction of price in the event of my sending you an order for a fair quantity, say, one dozen bottles.

Yours faithfully,
C. A——, M.D.

THE LANCET.

LONDON: SATURDAY, DECEMBER 22, 1917.

The Belgian Doctors' and Pharmacists' Relief Fund: The Second Appeal.[1]

WE publish this week a letter from the honorary officers and Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund, begging the immediate support of a further appeal for help. The letter merits the serious consideration it surely will receive from those to whom it is addressed; indeed, the signatories make out an unanswerable case for continued aid in their brief summary of their previous actions. At the close of 1914 the Fund was started by an appeal emanating from a committee fully representative of the medical and pharmaceutical professions in Great Britain and Ireland, and as a result about £20,000 were received almost entirely from members of those professions, the colonial and Indian share in this work of charity being nobly marked. *No further appeal has been issued*, but an Executive Committee for distribution purposes was appointed, and lists of the subscriptions, published regularly in the professional journals, were trusted to form a cogent reminder of the existence alike of the bitter need of the Belgian doctors and pharmacists, and of the methods of aid adopted. The money thus raised has in the course of three years been spent, first in relieving distress among the members of the medical and pharmaceutical professions, being Belgians, who had taken shelter in this country, often accompanied by considerable family circles; and, secondly, in helping to save from slow starvation those of our Belgian colleagues who, having remained at home, have been plunged into untold misery by the German savagery and usurpation. Latterly the proceeds of the Fund have been expended almost entirely in Belgium, care having been taken that the sums transmitted monthly should find their way into the hands of a competent professional committee in Brussels. The Executive Committee now state that only for one more month can these mensualities be continued. Economy has been unable to husband the sum collected in 1914 and 1915 for any longer time, though the administration expenses of the Fund have been practically nil. The definite position has been reached now that either the second appeal must be successful or the work must stop.

The difficulty of raising further and large sums of money from the medical and pharmaceutical professions in this country at the present moment is only too painfully clear. The two professions contain no very great number of persons, and many of these are undergoing through the war a disastrous decrease in income, while all of them are subjected, of course, to the impoverishing circumstances of raised prices and heavy taxation. We may be certain that these facts are well known to the Executive Committee of the Fund, who saw that their resources would suffice, on the scale of distribution adopted, until the end of this year, by which time it was hoped that the end of the struggle would be arriving. When this hope disappeared it was decided that a further appeal ought to be made, and at that juncture a letter reached Dr. H. A. DES VŒUX, honorary treasurer of the Fund, from Mr. W. B. POLAND, the Director for Europe of the Commission for Relief in Belgium, which made any other course absolutely unthinkable. We quote from that letter here, despite the fact that it appears elsewhere in full, because it is in itself, and without the added evidence of good management on the part of the Fund, a justification for the action of the Executive Committee in appealing immediately for renewed support. Mr. POLAND, emphasising the claim that Belgium has upon all her friends in the outside world who are trying to relieve her continually increasing distress, says:—

"The most difficult class to reach is the very class that your Fund in the past has ministered unto—namely, the families of the doctors and pharmacists who may not dig, to beg they are ashamed. If the supporters of your Fund knew how much actual suffering they had allayed, and how much potential moral and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. ..... The people who receive your kindness and charity are grateful in the extreme. Wave after wave of gratitude sweeps over the country. Some day you will know of it. ..... The funds from your society are paid over to a commission of eminent gentlemen of your profession and the distribution is under their personal supervision. The knowledge that their associates in England have not forgotten them is an inspiration to the whole profession at a time when moral support is perhaps as much needed even as food."

One practical answer only is possible to such a communication. The Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund must proceed to collect money for our Belgian colleagues suffering the tortures of want nigh to starvation, and of humiliation akin to shameful death. We know the needs of our own people, the needs that are present and those that are to come; and we should deplore anything that might detract from the chances of hearty support to such a movement as that now in progress in behalf of the War Emergency Fund of the Royal Medical Benevolent Fund. With the organised endeavour of the British Medical Association to support that Fund we have every sympathy, as we have endeavoured to show in another column. As far as lies in our power, we have helped, and will help, the Royal Medical Benevolent Fund in its great object. But at the same time, and at the worst of times for collecting money, we press on our readers the appeal for our Belgian colleagues.

[1] See p. 943.

Poor though this country may be under the stress of recent events, we are boundlessly rich in comparison with enslaved Belgium; and we have every confidence that once again the medical and pharmaceutical professions of Great Britain and Ireland will come to the assistance of the Belgian Doctors' and Pharmacists' Relief Fund.

Annotations.

"Ne quid nimis."

ELIZABETH GARRETT ANDERSON: PIONEER.

THE death of Dr. Elizabeth Garrett Anderson at the ripe old age of 81 years ends a career conterminous with the entrance of women into the medical profession. Elizabeth Garrett was the first woman to obtain a registrable medical qualification in this country, and although on the advice of the Attorney-General the Royal College of Physicians of London at the time "courteously declined" to admit her for examination or to grant her a licence to practise physic, she was able to obtain a high medical qualification at the University of Paris after having been through the ordeal of an anatomical dissection held in public by Professor Broca and his colleagues. Such courage and persistence could not fail of its reward. THE LANCET was among those who recognised at the time that Miss Garrett had "surmounted the great difficulties which surround the attainment of a complete method of education for women with singular energy and perseverance, at great cost, and after long years of arduous labour." The opening of a dispensary for women and children where she could put her attainments into useful practice followed as a matter of course, since the management of no public charity would at that time have ventured to offer her a staff position. Her return four years later by an overwhelming majority as a member of the Marylebone Division of the Metropolitan Education Board confirmed her public position. Controversy about women doctors was set aside to enable the appearance on the School Board of one whose warm sympathy for school-children was combined with a practical knowledge of the means for their physical and mental elevation. To the present generation the prejudices of the early "seventies" may well seem to belong to a different world altogether; but the revolution in outlook has occurred within the span of a single life-time, and Mrs. Garrett Anderson's work was the first stage in that medical emancipation of women, whose far-reaching effect is seen in the work of medical women in the present emergency. Not least seen in the war hospital under the command of Elizabeth Garrett Anderson's daughter, which is run exclusively by medical women and orderlies.

THE INFECTIOUSNESS OF TRENCH FEVER.

ALTHOUGH neither the infecting organism nor the method of conveying infection has been finally settled in the case of trench fever, suspicion centres increasingly round the louse, and thus it comes to be regarded as possible that soldiers arriving home from the Front with infected lice upon them may convey the disease to other members of their household. Information on this point is very desirable, and the small committee dealing with the study of trench fever at the Royal Army Medical College would be glad to know of any cases coming under the personal observation of our readers. We may well recall in this connexion that in Professor G. H. F. Nuttall's exhaustive study of the louse in the November number of *Parasitology*, it is stated that under favourable circumstances lice may even be distributed by the wind. V. Schilling first made the observation in 1916, and it has since been confirmed by other observers, one of whom narrates that after some unpleasant experience he made it a habit of examining lousy men while standing to windward of them. Information may be sent to Surgeon-General Sir David Bruce at the Royal Army Medical College, Grosvenor-road, London, S.W. 1.

THE CHRISTMAS CALORIE.

THE will to make Christmas a time of cheer in spite of calorific limitations will be a capital accompaniment to the national appeal to husband our resources. In the knowledge that the observance of a restricted dietary is furthering the great and high aims of the nation, the season should still be made a joyous one; aware that self-denial means a step to victory the nation will pass through the customary festive occasion with light diet but stout heart. It is quite certain that, as the suggested allowances stand, no harm, and most likely good, will accrue to the health of the community generally by keeping their bodily needs just within physiological bounds. Festive occasions celebrated by hearty feeding and drinking do not, as a rule, leave the individual in a higher state of health. There is nothing at all in the public health returns to show that any deterioration in the health of the public is taking place as a result of food restriction. The immediate future does not augur well for increased supplies, and therefore it would be a splendid patriotic effort if this year the great Christmas festival were allowed to pass as a day of determined sobriety and sacrifice. It is to be remembered also that to a large number Christmas-time means some days of rest from toil, and the sedentary life calls for a smaller requirement of food than the restless, active one. There is at that time less call for repair. The nation might well regard the season as a few days off from routine, which give a relief to taxed energies and therefore diminish the call for high calorific values.

SMALL CUTANEOUS ANEURYSMS AS A SIGN OF PREMATURE SENILITY.

IT is not uncommon to notice in elderly people the more or less insidious appearance on the skin of punctiform hæmorrhages, scattered irregularly or with a confluent tendency, and sometimes associated with small angiectases, particularly in situations most prone to impeded circulation, such as the legs. The changes in the arterial system and alteration in the condition of the skin in advancing age are well known, but hitherto few observers have drawn attention to the possibilities of changes in the walls of the cutaneous arteries. Professor Arullani,[1] of the University of Turin, has made some interesting histological researches on the skin of persons prematurely old from physical or intellectual overwork, progressive toxic diseases and various cachexiæ, and describes marked and constant changes both in the superficial and deeper layers. Apart from the dilated capillaries which are scattered at wide intervals on the surface, he found various degrees of dilatation in the lumen of

[1] Il Morgagni, Part I., Sept. 30th, 1917.

the arteries in the hypoderm, and noticeable damage of their coats, principally of the tunica media. These arteriole dilatations took the form of round, elliptical, or irregular swellings, with thickened walls and empty of blood contents. As a rule there was a direct relation between the dilatation of the vascular lumen and the changes in the parietes which were more noticeable in the larger dilatations, and involved all three coats. According to Professor Arullani, there can be no doubt that the formation of these small aneurysms explains the easy rupture of the arterial walls and the consequent cutaneous extravasation of blood, or, in other words, the pathology of the so-called "purpura senilis." Since the histological investigations were carried out in 12 patients who had no appreciable signs of sclerosis in the larger vessels, the presence of these cutaneous aneurysms constitute an early sign in the picture of the syndrome of arterio-sclerosis, and is of practical importance in the early treatment of that condition. A biopsy may thus throw considerable light from the point of view of an early diagnosis, and entails no more discomfort than many other clinical methods such as blood examinations. The result may be the inducing of prudence in the use of drugs which have a cardiokinetic action not only in the old but in those who are prematurely senile.

SYPHILIS AND HEART DISEASE.

AT a recent meeting of the Académie de Médecine of Paris Professor Gaucher claimed for syphilis a greater part in the production of cardiac disease than is generally admitted. He considered that lesions of the orifice and of the origin of the aorta were frequently syphilitic. Indeed, he asserted that all aortic lesions which are not consecutive to rheumatic endocarditis are syphilitic. In some cases aortic lesions are found in patients with only vague rheumatic antecedents and who are subject to pains which are called "rheumatic." But when such patients are carefully examined slight signs of tabes, particularly loss of knee-jerks, may be found. Moreover, the coexistence of marked tabes and aortic lesions is not very rare. Professor Gaucher further referred to the subjects of aortic disease who are liable to sudden death, not merely those with marked lesions, but those who show only a little dilatation of the aorta and an accentuated second sound. These signs, he thought, were often misunderstood, and many persons who died suddenly from apoplexia had old syphilitic disease of the aorta. Even a certain number of cases of hemiplegia attributed to syphilitic arteritis of the cerebral vessels were due to emboli originating in an unknown or misunderstood aortic lesion. Indeed, he considered sudden death as almost always due to syphilis, whether from the preceding mechanism, perforating myocarditis, or angina pectoris. The coronary arteritis which produces angina pectoris he considered always syphilitic. This was proved by the history, the sero-reaction, and above all by the result of treatment with mercury and iodide, which was often efficacious. Rupture of the heart he regarded as a result of gumma, and lesions of the bundle of His and the permanently slow pulse as also syphilitic. Hypertrophic sclerous myocarditis and the interstitial nephritis which accompanies it were, he thought, in most cases due to syphilis. Professor Gaucher did not report the observations in detail on which he relied to prove these views, but whether they are completely accepted or not they deserve to be widely known because of the frequently beneficial effect of antisyphilitic treatment with mercury and iodide which he has obtained in aortic and myocardial affections, even when there were concomitant arterial lesions, if the renal permeability was assured. Professor Gaucher also claimed that syphilis played a part in the production of mitral disease and related the following case. A man who consulted him for pityriasis of the scalp incidentally mentioned that he had heart disease of rheumatic origin, and had consulted a cardiac specialist, who prescribed digitalin. There was well compensated mitral regurgitation. Professor Gaucher then asked the patient if he had ever had syphilis. He replied that he had had a chancre, but was well treated, and permitted to marry by his doctor and had three healthy children. The knee-jerks were absent. Professor Gaucher prescribed a treatment for which the patient showed so much repugnance that in all probability he did not follow it. Professor Gaucher finally claimed that congenital syphilis played a part in the production of heart disease, and suggested that it should be looked for in cases of obscure origin.

THE WORK OF FOOD INSPECTION IN WAR-TIME.

IN the annual report of the medical officer of the Local Government Board for 1916–17 appears an appendix presenting a report by Dr. A. W. J. MacFadden on the work of inspectors of foods during the year. To carry out the scheme outlined in previous reports for the supervision of food for the Army continues to be the main occupation of the inspectors. In this matter valuable assistance is rendered by the medical officer of health and inspectors of the local authorities concerned, and it is stated that the general improvement in the conditions of food preparation previously recorded has been maintained and where necessary extended. Hygienic standards are enforced with most satisfactory results. Apparently vigilance is called for most over the sausage-making trade, especially amongst the small businesses, where it is necessary to ensure the maintenance of a clean handling of the materials. The supervision of canned meat manufacture is similarly carried out. The question of economising wheat flour in the making of bread and the use of substitutes has also received the practical attention of the department. An observation of considerable importance was made in September, 1916, by the Government laboratory chemist, Sir James Dobbie, who reported to Dr. MacFadden that a sample of phosphate baking powder, which had been sent with a tender for War Office supplies, had been found to contain as much as 32 parts of arsenic per million. It was subsequently found that the firm tendering the sample to the War Office were merely mixers of the various ingredients which enter into the composition of such baking powders. It is common knowledge that these powders have had previously as their acid basis cream of tartar, but owing to the shortage of this material the acid phosphate of calcium has largely come into requisition. Suspicion easily fell upon this agent, and investigation soon cleared up the matter, for all the arsenic found in the baking powder was contained in the acid calcium phosphate used. One sample of "cream of tartar substitute" (unmixed acid calcium phosphate) contained no less than 4½ grains of arsenic per lb., or 643 parts per million. The employment of arsenical sulphuric acid in the making of the acid phosphate

explained the contamination, but the fact that manufacturers knew that the product was arsenical is a most unsatisfactory feature of the case. As Dr. MacFadden points out, whatever extenuating circumstances, such as war-time conditions, might be pleaded for failing to secure a high standard of purity in all the acid phosphate manufactured, nothing can excuse the deliberate addition to an article intended for food purposes of a material known to be contaminated with a dangerous poison. By the activity of the Food and Drugs Acts authorities, however, the firms concerned were promptly made aware of the situation, and many of them had in their possession stocks of contaminated acid phosphate which had been returned to them by manufacturers and vendors of baking powders which had been reported against. An undertaking was eventually obtained that no acid phosphate which had not been analysed and found to conform with the generally recognised standards of purity as regards arsenic would be issued from the factory. The food inspection branch of the medical department at the Local Government Board may be congratulated on the efficient discharge of their duties in this matter, which, if they had not intervened, might well have led to serious consequences to the public.

OPERATIVE TREATMENT OF GANGRENE OF THE LUNG.

THE surgery of the lung is making rapid progress in our generation and no one has done more to advance it than Professor Sauerbruch, of Zurich. At a clinical meeting held on Dec. 4th, at the Cantonal Hospital, he showed a case of extensive gangrene of the lower lobe upon which he had operated a week earlier. The essential points to observe in such an operation are the protection of the pleura by tampons from secondary infection and the removal of large portions of the costal wall in order fully to expose the gangrenous surface and secure good drainage. The results of operative interference in such cases are fairly satisfactory, when it is remembered that a large proportion do not reach the surgeon until their condition is desperate. Sauerbruch lost 13 out of 37 on whom he operated. He also demonstrated a case of gunshot wound in which gangrene of small extent had occurred in the lung from which he therefore removed the bullet with ensuing recovery.

CHLOROFORM ADMINISTRATION.

THE claims of chloroform will probably never be denied so long as general anæsthetics are in use. It has in practice conveniences from its very potency, since this avoids the necessity for large amounts being carried and allows of the utmost simplicity in administration. Yet it is most desirable that convenience should not override the essential consideration of safety, and a few hundred, even a few thousand, successful administrations in private practice must not blind us to the well-proven risks of chloroform. Therefore we sympathise fully with the attitude taken up by the Section of Anæsthetics of the Royal Society of Medicine recently when it condemned the routine use of this drug in military hospitals.[1] Nor could any man who studies the evidence available fail to agree with Colonel J. F. Silk's conclusion. Yet for the many practitioners all over the country who have to give an occasional anæsthetic chloroform remains, and is likely to remain, the most valued standby. It is essential, then, that they should know how to minimise its risks. A correspondent draws our attention to one factor which is, in his opinion, most important. That is slowness in administration. We believe he is correct, provided that the slowness is combined with continuity. There should be no intermission in the inhalation of chloroform vapour once it is begun, and however slowly the administration is advanced, at any rate there must be no intervals in the procedure. It is mainly for this reason, the more easy achievement of continuity, that inhalers such as Junker's or Shipway's provide safer means for carrying on administration than do the simple drop-bottle and mask, although they are not so suitable for the beginning of induction. The question of safety is inseparable from that of the administrator's experience; probably better results accrue when a man accustomed only to chloroform employs chloroform than if such a man were to use a complicated and, to him, novel method of administering a safer drug.

[1] THE LANCET, 1917, ii., 716.

PARATONIC DEFORMATIONS OF THE HAND FOLLOWING ON INJURIES RECEIVED IN WAR.

THE latest number of the *Nouvelle Iconographie de la Salêptrière* contains a useful contribution to the vexed question of reflex paralysis. Professors Laignel-Lavastine and Dr. Paul Courbon have taken a series of 16 cases of arm injury with resulting clinical appearances of a peculiar nature, described originally by Professor Pierre Marie and Dr. Foix as paratonic paralysis. In these cases the familiar signs of a particular nerve lesion are mostly wanting, yet the condition does not conform to the usual varieties of hysterical palsy; it is one of hypotonus rather than paralysis, hypertonus rather than contracture. The attitude of the hand presents a fairly close resemblance to what is known as the accoucheur's hand. As an instance, the case may be taken of a soldier with fracture of the humerus and an incomplete section of the median. The hand was in the accoucheur attitude, with hypertonus in the ulnar group of muscles. The paresis of the median could not explain the hypertonus of the ulnar musculature according to the authors, it might be due to a reflex irritation of the coat of the brachial artery containing sympathetic fibres, at the level of the fracture of the humerus. In their 16 cases they have found motor impairment classifiable in four groups—organic, functional, mechanical, and reflex. In the first group there is no difficulty of interpretation; hypertonus, when it occurs, is due to direct irritation of a particular nerve trunk by the lesion. In the second group the neurologist recognises the familiar signs of hysterical paralysis either functional inactivity or hypertonus in a voluntarily adopted antalgic attitude of defence. The third group is simple enough; fibrous adhesions or cicatricial sclerotic retraction account for the symptoms. As for the fourth group, in the authors' experience it is rare in a pure and uncomplicated form (2 cases out of 16). On the other hand, it is very often associated with defects belonging to the other groups, but that should not lead to its being ignored or overlooked. In regard to the special characters of the physiognomy of the whole series the following points may be noted. The usual mask-like condition is one of combined hypotonus and

hypertonus of reflex origin consecutive to a lesion which does not involve any nerve trunk in a direct fashion. Hypothermy and a degree of cyanosis are the rule. Mechanical hyperexcitability of the involved muscles is commonly found, which is always increased by immersing the limb in running water at 15° C. for half an hour. On the other hand, warming the limb for ten minutes with water above 44° C. makes functional hyperexcitability disappear, but has no effect on true reflex hyperexcitability—an important observation if it is confirmed. The results of electrical examination are not of sufficient precision to be of diagnostic value. Decalcification of the phalanges by osteoporosis is very frequent, but certain observers declare this may occur from mere immobilisation of psychical origin. Sleep makes no difference on the paratonic attitude. Sensibility is as a rule unimpaired except where there is a hypoæsthesia manifestly of hysterical nature. In an ingenious analysis of the symptomatology in relation to the topography of wound and muscles involved, the authors suggest the possibility of inflammation at a distance. They point out that a muscle may be pierced by a foreign body without its tonus being in any way modified, provided the region where tonus is regulated is not implicated. According to the work of Alquier, this area is where muscle fibres and tendinous fibres join, and the authors consider their cases show a concordance between the sites of the lesions and the points of fibrotendinous junction of the muscles which are in hypertonus. Where this concordance is not traceable lymphatic channels may carry inflammation in the particular direction. In other words, it is preferable to think muscularly, as opposed to neurologically, in the consideration of these interesting varieties of impaired function after wounds of the arm, for the mere presence of reflex or organic disturbances is not sufficient justification for assigning all the phenomena to their action.

THE CAUSATION OF SO-CALLED VARICOSE ULCERS.

IN a paper which he read at the London Dermatological Society on Tuesday Dr. R. Prosser White discussed the causation of chronic ulcers of the legs. An analysis of 69 cases attending his clinic during the last five years, at ages varying from 10–67 years, showed that 14 occurred in males and 55 in females. In the 14 male cases he made a diagnosis as follows: syphilis, 6; trauma or sepsis, 3; eczema or psoriasis, 4; tubercle, 1. Varicosity was present in the ratio of 2 to 5. In the 55 female cases the causes assigned were: white swelling, 17; varicosity, 7; the same with a history of burst veins, 3; trauma, 9; eczema, 7; sepsis, 2; syphilis, 5; scald, 1; tubercle, 2; not diagnosed, 2. No less than 17 cases, therefore, gave a history of having suffered after confinement from phlegmasia dolens—a significant proportion when it is borne in mind that this condition occurs only once in every 400 cases of pregnancy. Dr. White concludes that phlegmasia or the secondary streptococcal infection following it are the conditions mainly responsible for the deep intractable ulcerations of women's legs.

THE King has granted unrestricted permission to Miss Lina Mary Potter, L.M.S.S.A., to wear the Insignia of the Fifth Class of the Order of St. Sava, conferred upon her by the King of Serbia in recognition of her services to the Serbian sick and wounded, under the auspices of the Scottish Women's Hospitals for Foreign Service.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND: THE SECOND APPEAL.

TO THE MEDICAL AND PHARMACEUTICAL PROFESSIONS OF GREAT BRITAIN AND IRELAND.

LADIES AND GENTLEMEN,—When at the close of 1914 the terrible plight of our professional colleagues in Belgium, overrun in circumstances of incredible brutality by the Germans, was brought to your notice, you responded generously to an appeal for the immediate creation of a Fund which should deal first with the grave necessities of those who had taken shelter with their families in this country, and secondly with the sufferings of those who remained in Belgium. The appeal of a committee representative of all sections of both professions was kept steadily before you in your professional journals, and the history and progress of the Fund up to February, 1917, which marked the opening of the third year of work, has been published as a pamphlet. This statement showed that by the first week in February, 1915, over £5000 were received, and that by the end of the first year of working £18,570 had reached the treasurer's hands. Further sums afterwards brought the total up to £20,000 by the end of the second year of working. *No appeals for subscriptions were sent out after the movement had been once inaugurated, and now the last financial statement shows that the Fund is practically exhausted.*

Of the value that the Fund has been to those for whom it was created in the directions designated there can be no doubt, and we call your attention to the appended letter from Mr. W. B. Poland, who has had the closest personal experience with the lamentable position of our Belgian colleagues, and who writes movingly of what your practical assistance has done. To us it seems impossible that we should not attempt to continue the work.

The present position, however, is that without further large and prompt subscriptions to the Fund we shall be unable to keep up those substantial monthly subsidies to Belgium to which the money has been mainly devoted. We are fully aware of the burden which the medical and pharmaceutical professions of this country are bearing; we know that several funds which have the highest claims upon our purses are at the present moment seeking, and rightly expecting, widespread assistance; but we none the less urge that the money should be found for carrying on acts of mercy—or rather we should say of bare justice—towards the doctors and pharmacists of Belgium, the little country which with unexampled heroism stood between the German onrush and the civilisation of Western Europe. Of the rightness of our second appeal we know that no doubt can exist, nor of the good that your money has done; while to the manner of the distribution of the Fund we can point with legitimate pride. All our administration has been carried out gratuitously, and the expenses at the end of the first year were only £12 and at the end of the second year only £50. We direct attention in this connexion to the very special wording of the certificate given by Messrs. Crewdson, Youatt and Howard after the examination of the accounts, with the books and vouchers of the Fund before them. This statement is also appended.

We beg, therefore, earnestly for immediate further subscriptions, that the benefits which we have been able to distribute for nearly three years may not suddenly cease at a time when they were never more urgently needed.

The address of the honorary treasurer of the Belgian Doctors' and Pharmacists' Relief Fund is Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W. 1, to whom all subscriptions should be sent. The honorary secretaries are Dr. S Squire Sprigge, THE LANCET Office, 423, Strand, London, W.C. 2, and Mr. W. J. Uglow Woolcock, the Pharmaceutical Society, 17, Bloomsbury-square, London, W.C. 1.

We are, Ladies and Gentlemen, your obedient servants,

RICKMAN J. GODLEE, Chairman,
President of the Royal Society of Medicine; late President of the Royal College of Surgeons of England.

H. A. DES VŒUX, Honorary Treasurer.

S. SQUIRE SPRIGGE, Editor of *The Lancet*. } Hon. Secs.

W. J. UGLOW WOOLCOCK, Secretary and Registrar of the Pharmaceutical Society. } Hon. Secs.

The following are the members of the Executive Committee elected at a meeting in London by a General Committee representing in the fullest way the two professions of Medicine and Pharmacy :—

T. BARLOW,
Late President of the Royal College of Physicians of London.
W. WATSON CHEYNE,
Late President of the Royal College of Surgeons of England.
MEREDITH TOWNSEND,
Representative of the Society of Apothecaries of London on the General Medical Council.
ALFRED PEARCE GOULD,
Late Vice-Chancellor of the University of London.
FREDERICK TAYLOR,
President of the Royal College of Physicians of London.
HERBERT SPENCER,
Obstetric Physician to University College Hospital, London.
T. JENNER VERRALL,
Direct Representative for England on the General Medical Council.
F. M. SANDWITH,
Gresham Professor of Medicine.
E T. NEATHERCOAT,
Vice-President of Pharmaceutical Society of Great Britain.
ALFRED COX,
Medical Secretary of the British Medical Association.
DAWSON WILLIAMS,
Editor of the *British Medical Journal*.
J. Y. W. MACALISTER,
Librarian of the Royal Society of Medicine.
C. O. HAWTHORNE,
Representing the Royal Faculty of Physicians and Surgeons of Glasgow.
J. P. GILMOUR,
Editor of the *Pharmaceutical Journal*.
WILLIAM RUSSELL,
President of the Royal College of Physicians of Edinburgh.
J. W. B. HODSDON,
Late President of the Royal College of Surgeons of Edinburgh.
JOSEPH O'CARROLL,
President of the Royal College of Physicians of Ireland.
WILLIAM TAYLOR,
President of the Royal College of Surgeons in Ireland.

LETTER FROM THE DIRECTOR IN EUROPE OF THE COMMISSION FOR RELIEF IN BELGIUM.

3, London Wall Buildings, London, E.C. 2, Nov. 20th, 1917.

Dr. H. A. Des Vœux, Honorary Treasurer of the Belgian Doctors' and Pharmacists' Relief Fund.

DEAR SIR,—We wish to emphasise the claim that Belgium has upon all the friends in the outside world who are trying to relieve her continually increasing distress. In spite of all we can do, her position to-day is more perilous than it has ever been, and far from relaxing our efforts we must, with renewed energy, see to it that every possible means of tiding over the starvation and destitution there is made use of. The most difficult class to reach is the very class that your Fund in the past has ministered unto—namely, the families of the doctors and pharmacists who may not dig, to beg they are ashamed. If the supporters of your Fund knew how much actual suffering they had allayed, and how much potential moral and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. This office is a gulf into which pours the stream of Belgian misery, and it would not be difficult to supply you with hundreds of testimonials as to the state of things there, but any of them tells the whole story: "The misery has become terrible and increases every day. It pursues us wherever we go. In the streets we see the emaciated figures of our neighbours; eyes sad, heads lowered. One would think that the people had aged twenty years by reason of these unmerited calamities." Another message comes: "Life becomes mere suffering; no liberty, no food. We are chained and starved in one. For three years we have fasted to such a point that now we scarcely recognise one another. The times are indeed hard."

The people who receive your kindness and charity are grateful in the extreme. Wave after wave of gratitude sweeps over the country. Some day you will know of it. Finally, it is needless to say that all the charities in Belgium are well administered—there is no leakage by the way. Only those who deserve it get relief, and never more than they need. The funds from your society are paid over to a commission of eminent gentlemen of your profession and the distribution is under their personal supervision. The knowledge that their associates in England have not forgotten them is an inspiration to the whole profession at a time when moral support is perhaps as much needed even as food.

Faithfully yours,
(Signed) W. B. POLAND,
Director for Europe.

THE AUDITORS' STATEMENT OF THE PRESENT POSITION OF THE FUND.

TREASURER'S CASH ACCOUNT, 1ST JULY TO 30TH NOV., 1917.

1st July. To Balance...	£5477 13 4	By Relief	£
,, Interest...	34 0 7	,, Clothes	
		,, Administration expenses	
		,, Balance Cash at Bank ...	149
	£5511 13 11		£551

We have examined the above account with the books and vouchers of the Fund, and certify it to be correct according to the books. In our opinion the receipts and payments have been fully recorded, and we have compared the receipts with the published acknowledgments and have had produced to us certificates as to the correctness of the balance as shown. CREWDSON, YOUATT, AND HOWARD, Chartered Accountants, Auditors.

70*a*, Basinghall-street, London, E.C. 2, 5th Dec., 1917.

This pecuniary position corresponded with the estimate of the Committee, earlier in the year, that the funds in hand would enable a mensuality of £800 to be sent during 1917 to Belgium, but that the end of 1917 would see the practical exhaustion of the Fund.

SUBSCRIPTIONS RECEIVED TO THE SECOND APPEAL FOR THE FUND.

THE LANCET	£50 0
Medical Insurance Agency (Chairman: Dr. G. E. Hastip)	50 0

THE CONTROL OF VENEREAL DISEASES

The Neglect of Gonorrhœa.

Lieut.-Colonel E. T. Burke, at present serving with the Mesopotamian Expeditionary Force, writes of the danger which exists at the present time of attention being devoted too exclusively to syphilis to the neglect of gonorrhœa. There is a tendency both for medical and lay opinion to regard gonorrhœa as being, compared with syphilis, of slight national importance. In his opinion the reverse is the case. The following points summarise the position regarding syphilis :—

1. The public realise the seriousness of the disease inasmuch as the infected individual usually applies for treatment early.
2. The medical profession realise the danger to the State that syphilis, and it is prepared to assist in every way in limiting it.
3. The State, since the publication of the Report of the Royal Commission, realises its responsibility in the matter, and is taking steps to deal with it.
4. Local authorities are formulating schemes to control it, to diagnose it, and to treat it, and educational campaigns are being instituted to enlighten the public with regard to venereal diseases.
5. The treatment of syphilis is specific.
6. The cure is rapid and permanent.
7. It can be stated when cure is completed and the patient no longer infective.
8. Treatment causes no inconvenience to the patient, and takes up little of the medical attendant's time.

These facts reduce the menace of syphilis considerably. The danger has been appreciated and means taken whereby to combat it. Unfortunately, with gonorrhœa the case is different. The disease is regarded as more of an inconvenience than anything else, the lesion being a superficial one and remaining so; and thus in many cases the patient hesitates to seek treatment at the hands of his own medical attendant and too often drifts into the hands of the prescribing chemist or the quack, or treats himself with a urethral syringe and by swallowing draughts of copaiba and sandalwood oil.

An acute gonorrhœa rapidly increases in severity and may—supposing that no complication has appeared—decline and the confirmed optimism of the patient makes him believe that he is now on the high road to complete recovery. As soon as discharge and the pain have disappeared the patient imagines that he is once more in healthy state, and resumes illicit intercourse or marital relations. In this way he may infect or cause to be infected a great number of people. The national danger of a man suffering from a gleet is enormous The rate of progression is geometrical, for if the original patient infects one or two woman she may in turn infect several men, each of whom may infect another woman, and so on.

The fact that the public have not appreciated the importance of gonorrhœa has reacted on the medical profession. There has, generally, been no great interest taken in the disease. Few practitioners have much experience of

treatment, and, with the exception of gonorrhœal arthritis, it seldom appears in the wards of a general hospital. The treatment of gonorrhœa is something more than the treatment of its symptoms. Cure is not attained until the urethra is completely free from the gonococcus. In the vast majority of cases treated no attempt is made to ascertain as to the presence or absence of gonococci, but the patient and the medical attendant rest satisfied with the disappearance of the grosser symptoms.

The difficulty both of diagnosis and treatment of gonorrhœa in the female is enormous, and it is safe to attribute a great deal of gynæcological trouble to former undiagnosed and untreated gonococcal infection. The following points summarise the present condition of gonorrhœa:—

1. The public are uneducated as to the importance of the disease.
2. The medical profession are not so well educated regarding diagnosis and treatment of gonorrhœa as of syphilis.
3. There is no specific treatment.
4. The best treatment is expensive and demands a skill and an amount of time not at the disposal of the general practitioner.
5. To state when the patient is non-infective is extremely difficult.
6. Under inefficient treatment the disease becomes chronic and the patient, unknown to himself, remains capable of infecting others.
7. Gonorrhœa in the female often goes undiagnosed and treatment is notoriously difficult.
8. The prevalence of treatment by chemists, quacks, and the patient himself constitutes a great danger.

For these reasons, which apply with special force only to gonorrhœa in contra-distinction to syphilis, Colonel Burke holds that the former disease ought at the present moment to be regarded with greater anxiety than the latter. It is now, when the machinery is in the course of erection for dealing with the whole problem, that the claims of gonorrhœa should not be lost sight of as they have been in the past.

The Treatment of Syphilis.

The article on the Treatment of Syphilis, by Lieutenant-Colonel L. W. Harrison, in the July number of the *Quarterly Journal of Medicine*, is a careful and practical presentation of an important subject, and is one that no practitioner concerned in the treatment of syphilis can afford to neglect. The history of the introduction of the newer remedies is briefly outlined, and then full details of the various methods of administration, with their advantages and disadvantages, are given. The comparative value of different methods of treatment, the nature of the by-effects of each, and the precautions necessary to obviate or lessen them, are all critically examined. The contra-indications of the arsenical preparations are also clearly described. The concluding section gives some useful details of the general arrangement of syphilitic cases, those in which there is no clinical evidence of disease of the central nervous system being differentiated from those in which such symptoms are present. A useful bibliography with 150 references is appended to the article.

The Crèche and Acquired Syphilis in Infants.

Dr. George Pernet, in a paper upon this subject, published in the *British Journal of Children's Diseases* (July–September, 1917, p. 168), sounds a useful note of warning to be on the look-out for cases of this character, and especially, if possible, to prevent their admission to, or at any rate their power of infection within, the artificial surroundings and circumstances of the crèche. He instances the following two cases which had recently come to his notice:—

The first was a male aged 18 months. For the fortnight previous to examination there had been "boils" upon the buttocks. When seen the skin of the child was found to be more or less involved from head to foot. The type seemed to be like that of a generalised dermatitis exfoliativa, but the tint was sombre and dark, the affected areas looked infiltrated, and the squamæ were rather adherent. Altogether it did not fall in with dermatitis exfoliativa and something seemed to suggest syphilis. There was, however, no question of congenital syphilis. The mother was healthy, had had nine children and no miscarriages, and her Wassermann reaction was negative. Further, the age of the child was against it, as the congenital type always evidences itself before the third or, at latest, sixth month. Against dermatitis exfoliativa neonatorum was the experience that this condition nearly always occurs within the first few weeks of life and also is generally fatal. The baby was put on mercury and rapidly improved.

The second case was a male aged 9 months. For the rash, which appeared on the arms, face, and fingers three months previously, the mother had been using sulphur ointment; there were, however, on examination no signs of scabies. The rash was papulo-macular, typical of acquired secondary syphilis. The peri-anal region was involved. The child had had a hoarse cry for three weeks. The Wassermann reaction was positive. This child also did very well on mercury. In neither of these cases could the source of infection be traced. In neither, fortunately, was the mother infected, as she was unable to suckle the child. Early diagnosis of these cases is obviously important. The early age of the child and the special tendency to rashes and skin troubles tend to make one ignore the possibility of venereal infection as a possible factor, though it is, perhaps, a counsel of perfection to forbid such infants the crèche.

Dr. Pernet suggests that certain precautions could be reasonably adopted which would lessen the danger of their presence. The parents and nurses should be warned of the danger of suckling them. Teats should not be bandied about, as is so often done, and the child should, of course, have its own feeding appliances.

The Supply of Salvarsan Products in U.S.A.

The Adamson Bill which Congress has just passed authorises the President to license American citizens to prepare and sell products patented by alien enemies. Dr. J. A. F. Schamberg, speaking at the Philadelphia College of Physicians, said that the dermatological laboratories had applied for a licence to distribute arsenobenzol. More than 125,000 doses had already been used in the United States, and it was hoped to reduce the price of the individual dose to $1.50 for doctors and 80 cents for hospitals. The high price of German manufactured salvarsan—over $4.50 an ampoule—has offered great inducement to counterfeiting, and a gigantic swindle was recently detected by an inspector of the New York Department of Health. A man calling himself a medical man was convicted of manufacturing fake neosalvarsan from common salt with addition of a trace of colouring matter. The label and circulars of the original Farbwerke product were very carefully reproduced so as to be only distinguishable by experts, while the scale on which traffic had been done may be gauged by the fact that 50,000 aluminium containers had been ordered. It is satisfactory to know that on this side of the Atlantic salvarsan products are issued on Board of Trade licence after examination of batches by the Medical Research Committee.

The Prophylaxis of Venereal Diseases in Italy.

Dr. Charles Ruata, the veteran professor of materia medica in the University of Perugia, has written to us supporting the observations made by Dr. G. Archdall Reid in THE LANCET of Nov. 3rd on the application of ordinary antiseptic methods to the prevention of venereal infection. As medical officer of two big convict prisons, he noted on taking up his position 33 years ago the frequency of venereal diseases among the 40 odd soldier guards. Dr. Ruata soon decided to lecture to them on the pathology of venereal diseases, particularly of syphilis, and including an explanation of Listerian methods. It is not necessary, he says, to use carbolic acid or any other antiseptic of the kind. Soap and water are sufficient when they are properly used. Dr. Ruata continues:—

When a man knows thoroughly the responsibility that he has for himself and for others he certainly takes every care to apply Lister well. Water and soap are always ready. The ointment of calomel is not practical at all: one cannot pretend that a man carries with him such an ointment. Since advising the use of soap and water I have had for 30 years no more cases of venereal disease among my guards. It seems to me that when all the soldiers, all the workmen, all the adult pupils of our schools are properly instructed in the pathology of venereal disease, this scourge of humanity will readily be stamped out.

Evidently the same need is present in Italy as here of exact instruction in the principles of surgical cleanliness.

Enlightenment Campaign.

At Sunderland the first meeting has been held of the new branch of the National Council for Combating Venereal Diseases. Under the auspices of the Birmingham Branch Colonel G. Barling, A.M.S., recently gave an address at which Mr. Neville Chamberlain presided.

New Schemes.

The scheme adopted by the Bristol city council has been approved by the Local Government Board and provides for six clinics a week, three at the Royal Infirmary and three at the General Hospital, with two beds for in-patients at each place. The sum to be paid to each institution is £637 10*s.* per annum, plus 6*s.* per occupied day for each bed. The total cost is provisionally estimated at £3150.

The Wolstanton and Burslem board of guardians have passed a resolution to the following effect:—

That subject to certain safeguards against abuse, the Public Assistance Authority should have power to detain cases of venereal disease when medically certified to be dangerous to others.

THE Queen has sent a Christmas donation of £10 each to the Chelsea Hospital for Women and the Royal Dental Hospital, Leicester-square.

Correspondence.

"Audi alteram partem."

ON THE "GREAT ASSISTANCE" OF AGGLUTINATION TESTS IN THE DIAGNOSIS OF ENTERIC IN ANTI-ENTERIC-INOCULATED INDIVIDUALS.

WITH SPECIAL REFERENCE TO DREYER'S METHOD, AND ALSO CERTAIN CRITICISMS BY CAPTAIN R. P. GARROW.

To the Editor of THE LANCET.

SIR,—THE LANCET of July 28th, 1917, contained a fifth communication by Captain Garrow, entitled "The Fallacies of Relying Solely on Agglutination Tests for Diagnosis of Typhoid Fever in Antityphoid-Inoculated Individuals, with a Special Reference to the Use of Dreyer's Method." In this he criticises the communications by several workers using the method, among others one by Dr. Cronin Lowe and myself upon "The Serum Reaction of Three Hundred Unselected Cases of 'Enteric' from the Eastern Mediterranean, with the Oxford Standard Agglutinable Cultures."[1]

I have been unable until now to comment upon these criticisms, some of which are unfair—no doubt unintentionally. Captain Garrow's argument seems to be as follows:—

1. We have "accepted," and "almost without question," what he alleges to be the "teaching of the Oxford School of Pathology," and, among other teachings, the "belief that an agglutination fluctuation of greater or less extent has a *pathognomonic significance*." Consequently, we do not realise that a diagnosis of enteric in the inoculated can only be made—when the enteric bacilli are not demonstrable—by *combining the clinical and serological evidence*.

2. The fact that we did diagnose on serological grounds alone "typhoid patients ('our patients,' says Captain Garrow) arriving convalescent in England" is an awful example of the "pathologist's lack of faith in clinical diagnosis."

3. The fact that we did diagnose a proportion of true typhoid fever (25 cases in 300) "higher than ever actually occurred in the Mediterranean" is an awful example of the absurdity of "relying solely upon agglutination tests."

4. As we did not know whether to diagnose certain cases as typhoid or not we "apparently" adopted a particular course, partly in order to *make* (sic) our "results correspond with Archibald's figures for blood cultures." By so doing we show the "cloven hoof" because the results of blood cultures are likely to give an *unduly* high proportion of typhoids and this is what we found!

I. It is not my place to consider whether Captain Garrow correctly describes the teaching of the Oxford School of Pathology. Dr. Lowe and I were not primarily concerned with that; *we confined ourselves mainly, and as far as possible, to the teaching in the Directions issued with the Emulsions* "on behalf of the Medical Research Committee" from Oxford (*vide* our Conclusion 16). The Directions do not state that diagnosis may be made by "relying solely upon agglutination tests" and by regarding fluctuations of small extent as "*pathognomonic*." Captain Garrow must prove it was thought that they would be interpreted in that way or that several of those using them did do so. Apart from this, we did not accept *all* the teaching of the Directions, for our paper concluded as follows: "We have confirmed all the statements" of the Directions "with one minor exception, ... *as far as our opportunities have permitted*" (italics mine) (Conclusion 16). Further, we did not accept what Captain Garrow alleges is the teaching of the Oxford School of Pathology that "an agglutination fluctuation of greater or less extent has a *pathognomonic significance*." On the contrary, we admitted the "possibility," as Tidy's work goes to show, "that the general lowering of 'resistance' which occurs in diseases associated with prolonged pyrexia may *sometimes* temporarily diminish the titre of 'inoculation' agglutinins," such fluctuation could not be "pathognomonic."

Again, in trying to explain why a paratyphoid infection often increased typhoid inoculation agglutinins we referred to some former work by Dreyer and Walker, who found if an animal immunised with one micro-organism be subsequently inoculated with another micro-organism "its agglutination titre for the first micro-organism exhibits a new rapid rise of greater or less extent and pursues a curve similar to the ordinary inoculation curve." We suggested that the increase in typhoid inoculation agglutinins was, in the words used by Dreyer and Walker when referring to their experiments, "due to a reaction of a general non-specific character," such fluctuation could not be "pathognomonic." It seemed unnecessary to refer to other well-known agglutination fallacies often mentioned in text-books; for example, the occasional great delay in the appearance of typhoid agglutinins in cases of typhoid, or the rare appearance of typhoid agglutinins in acute tuberculosis: I met with a case apparently of this sort some years ago. Though we did not say so, it is also possible that severe fatigue, starvation, cold, alcoholic excess and "indisposition" and other *factors*, may *sometimes* affect the titre of "inoculation" agglutinins. We do not know. Let us "wait and see," or better, as we are not statesmen—let us "try and see"!

Because we did not know whether "an agglutination fluctuation of greater or less extent has a *pathognomonic significance*" and because we hold the same views as Captain Garrow, "that in cases which are 'negative' bacteriologically, diagnosis should rest upon combined clinical and serological observations, and not as a rule on the results of one or other methods alone," our last conclusion but one was as follows: "The prophylactic use of mixed paratyphoid vaccine will undoubtedly increase the difficulty of diagnosing paratyphoid, as typhoid vaccine has done in the case of typhoid. The difficulty will be greatest in those mild cases which occur, especially in the partly protected, where the infecting bacteria cannot be demonstrated. Repeated serological tests will be of *great assistance* in the diagnosis (italics mine). The most suitable method for routine work in war-time is Dreyer's with the Oxford emulsions" (Conclusion 15).

Captain Garrow omits all reference to this statement, which, because of its great practical importance, was placed near the very end of our paper. He has led his readers to infer that we advocate the general practice of "relying solely by agglutination tests for diagnosis of typhoid fever in antityphoid inoculated individuals." We do not advocate any such procedure. I, for one, have always taught, as my own students can bear witness, the necessity of considering serological and certain other laboratory tests as of "great assistance in diagnosis," but not infallible. The fact that before devoting myself entirely to pathology I was for four years an honorary assistant physician is only one of the reasons why I believe in the close coöperation of the laboratory and the clinician.

The necessity of repeated agglutination tests in antityphoid inoculated patients with continued fever as an aid to diagnosis, was laid down by the pioneer work of R.A.M.C. officers in India, as D. Harvey and Grattan. The necessity of repeated tests was first officially recognised in an Indian report published in 1910, which says that in such cases of "continued fever ..... practically no information is given in the statement Widal positive 1/40," consequently "an agglutination chart should be kept, the results being carefully recorded two or three times weekly during the illness."[2]

II. Before considering Captain Garrow's second point, that we actually *did* "rely solely on agglutination tests" to diagnose our patients, and show a "lack of faith in clinical diagnosis," and did not in practice recognise the necessity of combining clinical and serological observations, it is necessary to make an explanation. We were under a misapprehension concerning the meaning of the term "enteric."

In November, 1915, at the beginning of our observations, we were struck by the fact that the majority of cases were called "enteric." We thought this meant typhoid, for "enteric" was the term suggested by the Royal College of Physicians for the proper *registration* of "typhoid." (See last edition of "Nomenclature of Diseases, 1906.") We did not then know that the D.M.S. of the Eastern Mediterranean had given instructions that the term

[1] THE LANCET, August 3rd, 1916.

[2] Annual Reports of Divisional Sanitary Officers and Enteric Depôts, 1910. Simla: Government Central Branch Press.

"enteric" should be used to include paratyphoid as well as typhoid. It is true in our paper we too employed the term "enteric" in the new sense, but we acted upon Dr. Leonard Guthrie's letter to THE LANCET.[3] Nevertheless, it is my impression that some of the medical officers in the Eastern Mediterranean arrived freshly from England, who knew little or nothing of paratyphoid, and who had not yet fully realised the value of antityphoid inoculation, actually thought their cases were suffering from typhoid, although they called them enteric. This, however, is unimportant.

Now we have always believed in the value of antityphoid inoculation. Indeed one of us, shortly after a certain notorious Germ-Hun advertisement, had twice pointed out its advantages in the lay press so strongly,[4] that he was attacked in a specially written booklet, which was distributed widely in Liverpool; its author, a medical man, displayed his unusual intelligence by saying that "the germs of typhoid fever have never been proved to exist"! We thought it was right therefore as part of our investigation to attempt to diagnose as far as possible the number of typhoid and paratyphoid infections. Such an attempt seemed specially desirable as no statistics of those infections in the Eastern Mediterranean had yet been published; indeed, the weighty ones collected by Martin and Upjohn did not appear till September, 1916. So far as I am aware, no official intimation came to the special enteric hospitals in Liverpool or elsewhere in England that the Mediterranean cases of "enteric" arriving between October and December, 1915, were—if they ever had enteric—mainly paratyphoid and rarely typhoid. For example, there arrived at two enteric hospitals in Liverpool and Southport during those months 247 cases of supposed enteric, 210 were sent in as enteric, 4 as typhoid, 16 as paratyphoid, 15 as enteric and dysentery, 2 as paratyphoid and dysentery; and that was practically all the information the medical officers treating them received.

We imagined after writing in Conclusion 15 "repeated agglutination tests will be of great assistance to the diagnosis," instead of "will make the diagnosis," everyone would understand that though we relied "solely on agglutination tests" in *attempting* to diagnose our 300 patients, we did so *because there were no other means available*. We actually said "because practically all were 'convalescent' nothing could be learned by blood cultures, and very little by examining the excreta, we *attemvted* (italics mine) to arrive at a bacteriological and therefore correct diagnosis, by testing the agglutination reactions." We used the word "attempt" designedly, because we realised the difficulty of diagnosis in convalescence and by serological tests alone.

Further, in order to justify our attempt at re-diagnosis, and to avoid being accused of "lack of faith in clinical diagnosis"—as we have been accused—we took the precaution of saying "the diagnosis of typhoid" (enteric would have been better) "in the Eastern Mediterranean was *less reliable than usual*" during the "summer" of 1915, because (1) "it was only controlled by blood cultures in about 10 per cent.," though in a later series of Eastern Mediterranean cases "not included in our paper," "34 per cent. gave a history of blood cultures," due, no doubt, to improved medical organisation, (2) the serological controls which were carried out in about 40 per cent. were, we believe, unsatisfactory, (3) "pyrexia of unknown origin is frequent in hot climates," and fully one-third had a history of "acute dysentery." Captain Garrow, to strengthen his case against us, the pathologists, omits any reference to these statements.

A very high authority has informed me in writing that there were occasions during the outbreak when "cases passing 'blood and slime' were diagnosed as dysentery and those suffering from continued fevers without these objective symptoms were returned as enteric, i.e., on clinical grounds." It is a fact that owing to the exigencies of war the diagnosis in a large proportion of our "enterics" was merely tentative. Therefore, our *attempt* at re-diagnosis by serological tests alone was perfectly justified, for we only found enteric bacilli in 14 cases, 2 being typhoid and 12 paratyphoid. It does not show a "lack of faith in clinical diagnosis," nor that we advocate "relying solely on agglutination tests," as Captain Garrow's criticism leads his readers to think.

Captain Garrow asserts we accepted the teaching of the Oxford School "almost without question." On the contrary, we made 3000 tests, we questioned many statements in the Directions "*as far as our opportunities permitted*," such as the problem of co-agglutination, the accuracy of the technique, we even "furnished," as Captain Garrow once demanded, "agglutination results controlled by blood culture," so that the data obtained "might guide to the interpretation of agglutination results in other cases in which blood cultures failed to give a diagnosis," though in our 14 cases the enteric bacilli were isolated mainly from the fæces.

III. In order to study by collective methods the variation in typhoid agglutinins and appreciate as far as possible their significance, we analysed the 133 cases which agglutinated typhoid only, and were tested at least twice. There were 27 in which the agglutination titre fell one tube—i.e., diminished slightly. We had great difficulty in deciding whether these cases should be regarded as probably typhoid or not.

I will first give Captain Garrow's interpretation of our solution: "3. In the summary one-half these (i.e., 14 cases) are assumed (!!) to have been infected with typhoid." (Observe the two!!) We actually said, "*even if* (italics mine) we assume that as many as half ..... were also infected with typhoid bacilli." Captain Garrow's omission of the two words "even" and "if," *both* of which were deliberately used to qualify the whole sentence, must be accidental. But this omission is characteristic of the hasty and unintentionally unfair way he has represented some of our statements. Captain Garrow says further on, these cases "are assumed" to be typhoid (which they were not), apparently (1) on the sporting ground that they considered the "odds were even"; and (2) "with the object of making their results correspond with Archibald's figures for blood cultures." The division of the paragraph into two parts is mine; let us consider Part I.

As already stated, we had great difficulty in classifying these cases, but as the fall in titre was "so slight" we wrote: "It is in the majority most probably due to a gradual normal disappearance of inoculation agglutinins, or to technical error, and not to active typhoid infection." Nevertheless, though we believed the "majority" were *not* typhoid it seemed a fair and practical compromise, to halve the number of the "27 other cases," not on a "sporting ground," but in order to avoid being accused of making our statistics *too favourable for antityphoid inoculation!* Has Captain Garrow any sense of humour? Even after halving them, we took the precaution of referring to them later as "doubtful cases" (Conclusion 11).

Captain Garrow concludes that we have "serologically diagnosed" 25 cases of typhoid fever in antityphoid inoculated convalescents in the Mediterranean, which he says "represent about 16 per cent." This is untrue. We actually diagnosed 11 cases or less. Conclusion 11 reads: "Of 133 examined at least twice, *11* showed a marked fall or rise in titre, demonstrating that *almost all*, if not all, had a recent typhoid infection. But *even including doubtful cases*, not more than 10 per cent. of the 300 showed evidence of recent typhoid infection. This percentage, however, would have been increased had the first examination taken place sooner, but so also would the percentage of paratyphoid cases" (italics mine). The words "almost all" were used deliberately because we realised there might possibly be *other* explanations of "the marked fall or rise in titre." The "doubtful cases" have already been alluded to; even *including* them the case for antityphoid vaccine was overwhelming.

It is astonishing that Captain Garrow omits to quote *our* figures, 10 per cent. and 11, and as given in Conclusion 11, which summarises our results to the best of our ability. Of course he is quite fair in giving *his* interpretation of these results to try to prove his case. But he does not realise that he is quite unfair in suppressing *our* interpretation of them, and so misleading his readers as to what we really said. In passing, Captain Garrow is incorrect in assuming that *all* the 25 men were inoculated. We questioned 240 of our cases and said: "1 refused inoculation; 1 was not inoculated; 4 were not sure"; we do not

[3] "Enteric Fever: (*a*) Typhoid Fever; (*b*) Paratyphoid Fever." See 1916 edition, "Nomenclature and Classification of Diseases," Roy. Coll. Physicians. At present in the press. THE LANCET, 1916, vol. i., p. 887.

[4] Microbes, the War and the National Neglect of Science, C. Tinling and Co., Limited, Liverpool and London, 1916.

know whether the remaining 60 were inoculated—neither does he. It is a fact that a percentage did escape inoculation; thus Archibald had 9 and Walker Hall 6 bacteriologically proved cases of typhoid among the *uninoculated* from the Mediterranean.

IV. And now for the cloven hoof! Captain Garrow says we "apparently" halved the cases "also with the object of *making* their results correspond with Archibald's figures from blood cultures"! This statement is untrue. After reading it I should not have been greatly surprised had he said when we showed "paratyphoid B infections were commoner than paratyphoid A till November, after which the reverse obtained"—Glynn and Lowe appeared to have *made* their results correspond with Archibald's figures for blood cultures." Captain Garrow evidently refers to the following sentence: "Our proportion of one typhoid to not less than about 4 or 5 paratyphoid cases is corroborated by Archibald's figures for blood cultures," his proportion being 1 to 6·4. In other words, even if we included the *doubtful* typhoids and made the worst possible cases *against* anti-typhoid inoculation, yet our serological evidence proved, as Archibald's hæmological evidence proved, that paratyphoid infections were in the great majority. As a matter of fact, excluding doubtful cases, we diagnosed 11 typhoids (3·7 per cent.) and 110 paratyphoids (37 per cent.), or a proportion of 1–10. Martin and Upjohn, in a series of 350 cases, all of which were believed to be enteric, diagnosed 7 per cent. typhoid and 93 per cent. paratyphoid, a proportion of 1–13. Fortunately for us their figures were published *after* ours! Perhaps our meaning might have been better expressed. Still Captain Garrow would have displayed more courtesy by omitting his innuendo, especially as it is evident, from his use of the word "apparently," that he was not sure of his ground.

When referring to the six cases agglutinating typhoid only, which showed a marked steady fall in titre, we said this was "conclusive evidence of a recent typhoid infection." Here we have, in fact, regarded a certain type of agglutination fluctuation as pathognomonic. We admit the evidence is *not* conclusive, and that our statement is inconsistent with the others in our paper. It is noteworthy, however, that Captain Garrow himself is also inconsistent on this very point. He writes at the beginning of his paper concerning "inoculated soldiers" "it is my opinion that, in cases which are 'negative' bacteriologically, diagnosis should rest on combined clinical and serological observations, and not, *as a rule*, on the results of one or other method alone."[5] Therefore, he admits that certain types of agglutination fluctuations may exceptionally be pathognomonic, and that a diagnosis may exceptionally be made by "relying solely" upon them. But in Conclusion 6 of this same paper he says: "It cannot be too strongly insisted upon that agglutination tests (by any method) *cannot* be relied upon *solely* to furnish a diagnosis of enteric infections against which the patients have been inoculated"! (italics mine).

The general accuracy of Dreyer's technique and the general soundness of some of the Directions, and also the fact that, in spite of the handicap of examinations made during convalescence, valuable information could be obtained by a collective investigation, is indirectly demonstrated in the following observations. Eighty-three cases agglutinating either paratyphoid A or B were examined at least twice; the paratyphoid titres presumably from infection fell during an average interval of 4 4 weeks in 81 9 per cent.; 48 per cent. fell markedly; but the typhoid titre presumably from inoculation fell in only 16·6 per cent., and only 1·4 per cent. fell markedly.

I ventured to state in a letter to THE LANCET: "Had Dreyer's method been employed earlier in the war far fewer soldiers would have been invalided home from the East with a diagnosis of typhoid fever"[6]; the word should have been "enteric." Captain Garrow in the summary concludes: (7) "The official adoption of Dreyer's technique as a standard agglutination technique in the Army, together with the teaching of the Oxford School of Pathology as to the diagnostic significance of the agglutination fluctuation in an inoculated soldier, would be disastrous to enteric statistics in the Army." He does not object to Dreyer's technique, for he wrote in an earlier communication: "I believe that the Oxford School of Pathology have, by working up this method to its present state of accuracy, performed a great service to medicine in general and military medicine in particular." I agree with every word of that.

As previously stated, we were not concerned with Captain Garrow's interpretation of what the Oxford School teaches. I still believe that had the Technique and Directions been extensively used in 1915 the result would have been beneficial—not only would fewer soldiers have been invalided as "enteric," but many more of those who had enteric would have been correctly differentiated into typhoid, paratyphoid A, and paratyphoid B. I know from personal experience that some of those who went East to do laboratory work had neither the special training nor knowledge to fit them for such responsible duties. Laboratory courses for R.A.M.C. officers were not so common in 1914–15 as they are now, which is in itself a recognition of the want of training in the earlier days. The War Office, at any rate, do *not* think that the results of employing Dreyer's technique "would be disastrous to the enteric statistics in the Army," for in September, 1916, an A.C.I. was issued telling how the Oxford emulsions with, of course, the Directions could be obtained at the home laboratories. When someone introduces a new scientific method, and a second subsequently supports it strongly, a third often "smells a rat." There is no rat—in our case! We do not know Professor Dreyer except by reputation, we hardly know Dr. Ainley Walker. We had no interest in the Oxford emulsions. We were not asked by any person or body to investigate them. We did so entirely "on our own," and as impartially as we hope later to have the honour of trying Captain Garrow's special agglutination machine. Perhaps, like the historic sons of a certain gentleman who came to a sudden and bad end, we took "too much upon" ourselves. Still, we desired to direct more attention to the many and great advantages of Dreyer's technique and the emulsions for routine work in war time, and the general soundness of the Directions "as far as our opportunities permitted" us to express an opinion, for we were convinced that they would be of "great assistance" in the diagnosis of enteric in antityphoid inoculated individuals, though they may eventually be found capable of some improvement.

We admit being misled regarding the term "enteric"; we admit being inconsistent in practice on one point, as Captain Garrow has been inconsistent in principle. It may not have been sufficiently clear to all, that though we did in fact "attempt" a diagnosis of typhoid by relying solely upon certain types of agglutinin fluctuation and in convalescence, we did so because the circumstances were exceptional, but did not, and do not, advocate such a proceeding "as a rule."

We are indebted to Captain Garrow for enabling us to explain these points, but we decline to be drawn into a controversy with him. We fully recognise Captain Garrow's scientific and critical ability, and it is a pleasure to record our information that he was among the first in a certain Mediterranean area to recognise in the autumn of 1915 that cases called enteric—if they had enteric—were mainly paratyphoid and rarely typhoid. We, in our conceit, imagine that we also were among some of the first to recognise the same thing independently in England, and by serological tests alone. Nevertheless, we find it difficult to understand the tone, or, to use a more fashionable word, the "psychology," of some of Captain Garrow's methods of criticism. He formerly wrote: "I do not believe that personal emotions such as love or hate can possibly enter into discussions on purely scientific matters." After such an utterance, if for no other reason, we had a right to expect throughout the scrupulous fairness of an upright judge, not on occasion the omission, the misrepresentation, and the innuendo of counsel for the prosecution! Captain Garrow would make a brilliant lawyer.

We shall always read Captain Garrow's future communications with profit. We shall read them with pleasure if he will only admit that, in the heat of the game, he has sometimes unintentionally been "off-side," and, like a true sportsman, make an "amende honorable."

I am, Sir, yours faithfully,

ERNEST GLYNN.

THE PERSONATION OF MEDICAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR, — The characteristics of medical impersonators mentioned in the leading article in your issue of Dec. 8th do not at all tally with those of the only case I have met, Siddons, and the impressions he left on me after working on the same medical recruiting board for three months may perhaps be of some interest. Had Siddons read "Behind the German Veil," by Beaufort, the man who lately bluffed his way all over Germany, visiting Hindenburg, and inspecting the German fleet without at any time being in possession of a pass, he could not have improved his tactics, having nothing to learn from any past-master of bluff. Far from avoiding recognition and exposure by keeping in the background, he was for ever hustling himself into the limelight. When he decided to join a medical board he chose that nearest to headquarters, and entered on his duties, as it were, under the august nose of authority, where no one would dream of looking for such as him.

Siddons was a powerfully built, thick-set man with a strong personality, a clever-looking face, and rather overbearing manners. I did not know him socially, as his personality did not attract me, but I should not be surprised to hear that he was a good poker player. Anyhow, with no cards in his hand he managed to bluff us all. He was always ready to back up his opinions by argument, and the only evidence he showed of insufficient education was in the occasional mis-spelling of medical terms, but I had previously found eccentricities in this respect so unexpectedly common amongst my colleagues in various parts of the country that it carried no weight with me. He was very keen about his work and always eager to examine or discuss anything rare and to pick up any useful information, such as the gleanings I gave him from Mackenzie's latest book on the heart. As might now be considered only natural on the principle of "set a thief to catch a thief," he had a distinct *flair* for malingerers, and not unjustifiably rather prided himself on his results.

As regards his capabilities of diagnosis, in one case of suspected tuberculosis where there was a conflict of opinion the tuberculosis officer to whom the case was referred supported his diagnosis. The only time I believe I had him was one afternoon, when two men in immediate succession proved to have complete transposition of viscera, and even now I am not quite sure that he did not bluff me.

It is suggested in the leading article that he underclassed recruits in exchange for bribes. This is not so. Under the system we worked, one man only being responsible for part of the examination, such a thing would not only have been difficult but dangerous, because we were working under a president as keen as any terrier after rats to pounce on one or other of us for faults of commission or omission. From what we were able to find out afterwards his method was not so crude and inartistic as such a statement would imply. He extracted rewards afterwards, by skilful innuendo and suggestions of undue influence, from men who had properly been classed low: a really far cleverer procedure. Although he was a man I did not like, to give the devil his due, I think all who worked with him are agreed that no doubt owing to a rather unsympathetic nature and a suspicion of fraud in others he was rather inclined to class recruits too high.

To any who may be surprised at his imposture remaining undetected so long I would suggest that the results of passing an easy qualifying examination and thereafter for years relying on a good bedside manner for success rather than the reading of medical literature may have something to do with the undoubted fact that Siddons's work as an examiner of recruits was distinctly above the average. He had very good judgment, was apparently all his life interested in medicine, and had his life been laid in times when the want of means is no bar to entering the profession his ending might have been very different. But had I needed it this experience would have taught me the difficulty of judging a man's qualifications from his capabilities.

I am, Sir, yours faithfully,

FRANCIS HEATHERLEY, M.B., B.S. Lond.,
Rock Ferry, Cheshire. Dec. 14th, 1917. F.R.C.S. Eng.

BACK PRESSURE AS A CONSEQUENCE AND AS A CAUSE OF HEART FAILURE.

To the Editor of THE LANCET.

SIR,—The appearance of Dr. Harrington Sainsbury's letter in your issue of Dec. 8th on the Theory of "Back Pressure" as a Consequence and as a Cause of Heart Failure suggests to me that your readers may be interested in another aspect of the means by which mechanical obstruction may possibly give rise to myocardial exhaustion and cardiac failure.

The point to which I would draw attention, and to which I have been greatly attracted for some time, may be put briefly in the form of a question as follows: "Is the distension of the auricle that occurs in connexion with mitral stenosis the exciting cause of the fibrillation of its wall?" No doubt an answer could be supplied by experimental research, but I am unfortunately not in a position to carry out the investigation necessary for the application of this inquiry. From the clinical point of view, however, it is possible to adduce a good deal of evidence in support of an affirmation of the view that has been brought in question. Thus auricular fibrillation rarely, if ever, occurs as an early manifestation of mitral stenosis; on the contrary, it almost invariably appears in the late stages of the valvular narrowing, when the intra-auricular pressure is greatly increased and the auricular distension is considerable, and when, therefore, there is well-marked stretching of the auricular walls. It is unnecessary to support these statements by clinical evidence, since it may be taken for granted that they will meet with general approval and assent.

Again, all treatment which has for its object the lowering of intra-auricular pressure, and hence the lessening of the stretching of the muscle fibres of the auricular wall (with the possible restoration of auricular tonus) tends to promote the disappearance of the fibrillation and the reappearance of the normal auricular rhythm. In point of fact, rest in bed, the administration of digitalis, free purgation, venesection, &c., either severally or collectively, are frequently instrumental in abolishing the abnormal rhythm and restoring the presystolic murmur. In these instances it is not an unreasonable supposition that the lessened stretching of the auricular wall is followed by some recovery of muscular tonus and resumed functional activity of the mural muscle fibres.

Lastly, there is the analogy which is presented by other hollow muscular organs when their cavities are distended and their walls put on the stretch by reason of obstruction to the discharge of their contents. For example, the stomach, the intestine, and the bladder not uncommonly undergo what may be termed hyper-distension, and in these circumstances fibrillary twitching of the muscular walls of these organs may be observed, which not improbably is closely allied to, if not identical with, the fibrillation that occurs in the case of the auricle under like conditions. It may be, too, that fibrillation is more readily evoked in degenerated unstriated, or partially striated, muscle fibres than in healthy contractile tissue.

Now apart from electrical stimulation, I am not aware that a satisfactory cause of the fibrillation of the auricle has so far been advanced, and I submit, for the reasons which have been given, that mechanical obstruction is a possible exciting causal factor of this condition. Moreover, should this view receive experimental confirmation a most interesting situation would arise, inasmuch as mechanical obstruction as a factor in the causation of heart disease, the *bête noire* of modern cardiology, would arise Phœnix-like from the ashes of the many fiery immolations that have been practised on it in recent years. I am, Sir, yours faithfully,

Upper Berkeley-street, W., Dec. 13th, 1917. E. H. COLBECK.

ETHER CLONUS.

To the Editor of THE LANCET.

SIR,—It would be interesting to know whether anæsthetists in military hospitals have found this curious and troublesome phenomenon more common among soldiers from overseas than it is among patients in civil hospitals. In my own limited experience it is. In a county hospital where I gave "open" ether as an anæsthetic about 1000 times, in the

years 1915–1917, the ether tremor only occurred in five cases. In this war hospital, recently opened, out of 41 operations performed under "open" ether anæsthesia, the tremor has occurred in three cases, not during induction, but after the establishment of full anæsthesia when the patient has been allowed to revert to a lighter degree of narcosis. Is it possible that active service under modern conditions may, in certain cases, induce a nervous condition favourable to the tremor? I first saw the phenomenon at Addenbrooke's Hospital, in 1880, when the late Sir George Humphry was amputating a leg. He was about to tie the vessels when the stump began to shake with great violence. Turning to the students, he remarked, "Gentlemen, this is a complication which I have never experienced before. Let us wait till it stops." Humphry had then about 30 years' experience of operations under anæsthetic, and it is rather remarkable that the condition had not already come under his observation.—I am, Sir, yours faithfully,

W. D. ANDERSON.

Fusehill War Hospital, Carlisle, Dec. 11th, 1917

THE SURGERY OF EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—In Lieutenant.-Colonel T. P. Dunhill's paper on exophthalmic goitre, which appeared in your issue of Dec. 15th, there is much of interest, and more of common-sense than usually appears in surgical pronouncements on the subject. The article naturally and necessarily contains several references to Robert McCarrison's recently-issued work on the thyroid gland. As the author is either in India or on the high seas, it would be a long time before he could receive the issue of THE LANCET and a very long time before you could receive his reply; and as I am not only intimately acquainted with his views, but am in a humble sense the literary godfather of the clinical portion of his book, I make no apology for claiming the right to speak for him in his absence. There is nothing so vapid as a belated rejoinder.

By way of prompt rejoinder I cannot do better than point out that there is nothing in Colonel Dunhill's article which could in any way modify the validity of the following paragraph, which occurs on p. 240 of McCarrison's book:—

> There is no reason to doubt but that a sufficiently extensive thyroidectomy such as is practised by Dunhill will mitigate those symptoms which may be due to hyperthyroidism on the one hand, or to perversion of the thyroid's secretion on the other. But we must realise the limitations of such an operation and not seek to credit it with the cure of a malady the cause of which it leaves untouched. Nor should the possibility of the subsequent appearance of thyroid deficiency be overlooked. In the present state of our knowledge such an extensive thyroidectomy may be the best we can do in a small proportion of cases, but if it must be done let it be done only when all else fails, and let its results be recorded with scientific precision.

Neither is there anything in Colonel Dunhill's article to which any reasonable physician could object. Briefly expressed, his message seems to be that an operation on the thyroid gland in Graves's disease is not only justifiable but obligatory when the symptoms become urgent. With this we can all afford to agree; McCarrison's point is that the symptoms would never arrive at that stage if the disease were properly treated in its earlier stages; that, if the "medical filter" did its work properly, the knives of the thyroidectomist would rust from disuse. With much less emphasis than the occasion would seem to warrant, McCarrison says:—

> I believe that surgery has a more rational place in the treatment of this disease than that of interference with the thyroid gland—namely, the correction of such conditions as chronic appendicitis, chronic gall-bladder inflammation, chronic septic tonsillitis, gastro-intestinal stagnation or other disorders which may obviously be benefited by it. For of what use would it have been to have removed the major part of the girl's thyroid, whose case we have considered in an earlier part of this section, and to have left her with such a degree of gastric stagnation as X ray examination revealed? Such an operation might have improved her condition temporarily, but without the correction of the stagnation it could not have restored her to health.

Lord Palmerston is credited with the remark that nothing could be more misleading than figures, except facts. In connexion with Graves's disease it is the unfortunate fashion to quote the figures of a physician who claimed as a proud fact that 50 per cent. of his cases were cured by ordinary medical means. I have not at the moment an opportunity of searching the records to discover the date on which these glad tidings of great joy were conveyed to a goitrous generation; but if there be a physician of to-day who by ordinary medical means cannot cure more than half the cases of exophthalmic goitre which come under his care, I can confidently recommend him to forsake medicine and take to surgery—or even to skittles.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 15th, 1917. LEONARD WILLIAMS.

THE FUTURE OF THE POOR-LAW.

To the Editor of THE LANCET.

SIR,—To my letter in THE LANCET of Nov. 17th under this heading I have had 114 replies. The question I asked was: "Do you wish the Poor-law to be merged into the present or future Insurance Act?" Two only of my correspondents answer "Yes." I have had 400 replies to a previous questionnaire, all saying that they do not wish for the proposed absorption of their service. There are about 5000 Poor-Law medical officers, the majority of whom must wake up if the wishes of the service are to be stated at all adequately. So far 500 members are practically unanimously against the notion of absorption.

I am, Sir, yours faithfully,

A. WITHERS GREEN,
Honorary Secretary, Poor-law Medical Officers' Association.
Wardrobe-place, London, E.C. 4.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

David McM. Dickson to be temporary Surgeon.

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. F. F. Muecke relinquishes the acting rank of Lieutenant-Colonel on reposting.

Temporary Lieutenants to be temporary Captains: A. W. P. Fitz, J. Paterson, J. R. Fleming, D. O. Richards, W. C. P. Barrett, G. O'S. Waddington, T. P. Lineham, L. G. White, M. Golding, W. Simpson, J. B. Lester, V. C. Montgomery, A. H. Macklin, W. D. Kirkwood, F. A. Godson, E. W. Hall, J. J. O'Mullane, W. M. G. Guinness, B. G. H. Connolly, C. L. Warke.

Temp. Hon. Lieut. C. G. Hitchcock to be temporary honorary Captain.

Officers relinquishing their commissions: Temp. Capts. J. B. Scott (on appointment under the Ministry of National Service), F. A. Anderson, M.C., D. Macnish, P. M. Ragg, A. F. Elliott, A. Burns, C. W. Ensor, H. A. Cutler, W. Jameson, A. R. Muir, R. E. Thomas, T. Davidson, A. J. Couper, C. C. Bullmore, F. E. Wynne, E. J. Aveling, G. Pollock, F. J. McGlade, R. S. Jenkins, T. W. G. Hogg, L. J. H. Oldmeadow, J. E. R. Orchard, J. J. Anning, A. J. Anderson (on account of ill-health), G. B. Flux (on account of ill-health). Temp. Lieuts.: W. T. Morton, W. L. Walker, T. B. Stedman, J. B. McEwan, R. C. de C. Wheeler.

SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: R. V. Clarke, W. Yeoman, M. A. White, S. C. Swinburne.

TERRITORIAL FORCE.

Major G. Hall, C.M.G., is restored to the establishment.

Capt. (temp. Major, acting Lieut.-Col.) W. D. Sturrock reverts to the temporary rank of Major on ceasing to command a Field Ambulance.

Capt. J. Gracie is seconded.

Capt. C. A. Moore is seconded.

Capt. J. H. Baldwin resigns his commission on account of ill-health, and is granted the honorary rank of Captain.

TERRITORIAL FORCE RESERVE.

Surgeon Lieut.-Col. (Hon. Surgeon Col.) T. McC. Foley, from R.F.A., to be Surgeon Lieutenant-Colonel.

Col. S. S. Hoyland, from A.M.S., to be Colonel.

Lieut.-Col. E. J. Lawless, from Field Ambulance, to be Lieutenant-Colonel.

Lieut.-Colonel W. B. Cockill, from Casualty Clearing Station, to be Lieutenant-Colonel.

Lieut.-Col. W. S. Sharpe, from Field Ambulance, to be Lieutenant-Colonel.

Lieut.-Col. E. T. Collins, from Field Ambulance, to be Lieutenant-Colonel.

Major J. J. Cox, from General Hospital, to be Major.

Major R. Starkey-Smith, from Field Ambulance, to be Major.

Major C. E. Goddard, from Sanitary Company, to be Major.

The undermentioned officers from attached R.A.M.C.:—To be Major: Major R. E. Williamson. To be Captains: Capts. F. W. Goodbody, W. E. L. Elliott, and J. Wallace (from Field Ambulance).

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers:—London Regiment: Lieut.-Col. J. Goldiing (temporary Lieutenant-Colonel, A.M.S.). Royal Army Medical Corps: Lieut.-Col. E. T. Collins, Major (temp. Lieut.-Col.) A. F. Sweaney, Lieut.-Col. C. E. Humphreys, Major D. Walker, Major J. E. Bain, Major G. Wilson, Major A. Fowler, Lieut.-Col. L. W. Pockett.

MUNIFICENT GIFT TO CARDIFF MEDICAL SCHOOL.—Miss Talbot, of Margam Abbey, Port Talbot, Glamorgan, has presented £30,000 to the Welsh Medical School, Cardiff, for the foundation of a Chair of Preventive Medicine.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. J. J. Shannon, R.A.M.C., attached Yeomanry, qualified at Edinburgh in the early part of 1916, and joined up shortly afterwards.

Capt. J. A. Edmond, R.A.M.C., was a student at Guy's Hospital, London, and qualified in 1910. After holding appointments at Guy's Hospital he practised at Catford, S.E.

Capt. A. Cowe, R.A.M.C., attached Lincolnshire Regiment, qualified at Edinburgh in 1913, and was in practice at Penicuik, Midlothian, prior to joining the R.A.M.C.

Capt. C. H. Robson, R.A.M.C., attached Gloucester Regiment, qualified at Durham in 1913, and was in practice at Whitley Bay, Northumberland, prior to joining up.

Died.

Capt. W. J. Corridon, Indian Subordinate Medical Department.

Missing.

Capt. F. B. Ryan, R.A.M.C., attached Royal Engineers.
Capt. F. M. Walker, M.C., R.A.M.C., attached Royal Horse Artillery.
Capt. D. R. Alexander, M.C., R.A.M.C., attd. Worcester Regt.
Capt. J. Davidson, R.A.M.C., attached K.R.R.C.
Capt. J. Ferguson, R.A.M.C., attached Liverpool Regiment.
Capt. C. R. Wills, R.A.M.C., attached Rifle Brigade.

Wounded.

Capt. A. J. McC. C. Morrison, R.A.M.C., attached Liverpool Regiment.
Capt. T. F. Craig, R.A.M.C.
Capt. W. Robertson, R.A.M.C., attached Duke of Wellington's Regiment.
Capt. J. N. Robins, R.A.M.C.
Capt. A. C. Ainsley, R.A.M.C., attached Yeomanry.
Capt. G. Allison, R.A.M.C., attached London Regiment.
Lieut.-Col. L. D. B. Cogan, M.C., R.A.M.C.
Capt. J. V. Cope, R.A.M.C., attached London Regiment.
Capt. D. J. Foley, R.A.M.C., attached London Regiment.
Capt. W. Fotheringham, R.A.M.C., attached London Regt.
Capt. P. J. Lane, M.C., R.A.M.C.
Capt. D. C. McArdle, R.A.M.C., attached London Regiment.
Capt. J. R. Tibbles, R.A.M.C., attached Buffs.
Capt. E. A. T. Green, R.A.M.C., attd. Seaforth Highlanders.
Lieut. B. Knowles, R.A.M.C., attached Middlesex Regiment.
Capt. W. S. Pickup, R.A.M.C., attd. Somerset Light Infantry.
Capt. F. P. Rankin, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. G. C. W. Harker, London Regiment, died from wounds, younger son of Dr. T. Harker, of Bournemouth, and late of Sydenham, London, S.E.

Lieut. C. Morse, Royal Engineers, killed in action, youngest son of Mr. T. H. Morse, F.R.C.S., of Deal.

Lieut. E. L. Naylor, South Staffordshire Regiment, elder son of Major A. J. Naylor, R.A.M.C., of Eltham, London, S.E.

THE HONOURS LIST.

The following awards to medical officers are announced. The acts of gallantry for which the awards were made are not yet published. All are members of the R.A.M.C. unless otherwise stated. The dates in parentheses, in those cases where bars have been awarded, refer to the number of THE LANCET in which a record of the original decoration will be found:—

Bar to the Distinguished Service Order.

Temp. Capt. (temp. Lt.-Col.) C. D. Pye Smith, D.S.O., M.C. (August 25th, 1917, p. 331).

Distinguished Service Order.

Temp. Capt. W. H. Lister, M.C.; Capt. W. H. Collins, Austr. A.M.C.; Major E. L. Hutchinson, Austr. A.M.C.; Major P. A. Maplestone, Austr. A.M.C.

Bar to the Military Cross.

Capt. R. T. Cæsar, M.C. (June 23rd, 1917, p. 969); Temp. Capt. J. M. Forsyth, M.C. (Sept. 30th, 1916, p. 620); Capt. C. Jacobs, M.C., Spec. Res. (July 28th, 1917, p. 136); Temp. Capt. D. H. Russell, M.C. (August 25th, 1917, p. 332); Temp. Capt. P. R. Woodhouse, M.C. (June 3rd, 1916, p. 1149).

Military Cross.

Temp. Capt. E. C. Abraham; Temp. Capt. W. R. Addis; Capt. M. T. Ascough; Lt. R. H. Baxter, New Zeal. M.C.; Temp. Capt. A. C. B. Biggs, attached Suff. Regt.; Temp. Capt. G. A. Birne; Temp. Lt. C. H. Booth; Temp. Capt. R. Briffault, attached York and Lanc. Regt.; Temp. Capt. G. E. Chissell; Temp. Capt. E. J. Clark, attached S. Staff. Regt.; Temp. Lt. A. P. Draper; Temp. Capt. F. P. Fisher; Temp. Capt. A. G. Forbes, S. Afr. M.C.; Capt. H. Foxton; Capt. R. D. Gawn; Capt. N. B. Graham, Spec. Res.; Lt. A. R. Hill, Spec. Res., attached Glouc. Regt.; Capt. W. P. Jepson, Spec. Res., attached Devon Regt.; Capt. F. W. Lumsden, New Zeal. M.C.; Capt. D. Macfadyen, Spec. Res.; Capt. H. A. Macmillan; Capt. J. McGhie, New Zeal. M.C.; Capt. J. McKay, Spec. Res., attached Bedf. Regt.; Temp. Surg. R. G. Morgan, R.M. Battn.; Capt. J. Pinder; Temp. Capt. C. L. G. Powell, attached E. Surrey Regt; Temp. Lt. (temp. Capt.) W. L. E. Reynolds; Capt. W. J. Scade, attached High. L.I.; Capt. S. L. Serpell, New Zeal. M.C.; Capt. C. N. Smith; Capt. W. L. Smith, Austr. A.M.C.; Temp. Capt. W. Steadman; Temp. Capt. F. N. Stewart; Temp. Lt. (temp. Capt.) R. I. Sullivan; Temp. Capt. N. C. Talbot; Capt. R. F. Walker, Spec. Res.; Temp. Capt. H. C. Watson; Temp. Lt. R. E. Whitting; Temp. Capt. F. E. S. Willis, attached Sea. Highrs.

THE FUTURE OF THE DISABLED SOLDIER.

In his very practical address on Technical Training for Disabled Soldiers and Sailors at the Royal Society of Arts on Dec. 12th Lord Charnwood began by summarising the numerical extent of the problem to be dealt with. After noting the fact that the total number of officers and men discharged from the Navy and Army as unfit for further service by the end of last September was about 225,000, he gave an analysis of the proportion of various kinds of disablement, which we reproduce here, as it is the basis on which any systemic solution of the problem must be built.

Number of Cases in Every 1000 Disabled Men (Excluding Officers) so far Discharged from Army or Navy During the War.

Cause of Disablement.

Injury to eyes (including an occasional case of total blindness)	32	Diseases of chest (including, say, 60 tubercular cases)	124
Amputation of leg	30	Rheumatism	50
Amputation of arm	19	Diseases of heart	110
Injury to leg not requiring amputation	121	Epilepsy	11
Injury to arm not requiring amputation	82	Nervous cases	47
Injury to hand not requiring amputation of whole hand	61	Insanity	9
Injury to head (including, say, six or seven paraplegic cases)	47	Deafness (partial or, in comparatively rare cases, total)	26
Hernia	7	Frost-bite (including cases of amputation, which are less than one-tenth of the whole)	10
Miscellaneous wounds and injuries (including, say, about five paraplegic cases)	53	Miscellaneous diseases (among which may be noted, besides a few paraplegic cases, Bright's disease, ulcer of stomach, debility, and varicose veins)	160
Total wounds and injuries	453	Total cases of disease	547

Total wounds and injuries and cases of disease 1000

Dealing with the opportunities provided for technical training, Lord Charnwood recalled the fact, on which it is impossible to lay too much stress, that in the experience of Pensions Committees there is as yet only a small proportion of disabled men willing to accept training, even when pressed upon them. This remains a disquieting feature of the problem. The broken man can, under the present abnormal labour conditions, find remunerative work of an unskilled nature, a blind-alley occupation which will inevitably land him in dire distress when the war is over and when the supply of undisabled and unpensioned soldiers, all wanting work, is unlimited. Lord Charnwood, therefore, rightly adjures Local War Pensions Committees not to work on routine lines, but to leave no stone unturned in insisting upon skilled training for their pensioners. We may recall that the Ministry of Labour has set apart special technical advisory committees to help the Pensions Committees in all such matters as the selection of candidates for training, the suitability of the training offered at technical schools and workshops, and on any other technical points which may arise. The student of the problem will also be greatly helped by a study of Dr. C. W. Hutt's "The Future of the Disabled Soldier,"[1] which has been written with the express object of preventing the degradation of the disabled soldier. In this book a full account is given of the training of the disabled man abroad and in the United Kingdom, and of the varying ways in which occupation may be adapted to physical defect. The subject is a tremendous and pressing one to which much attention will have to be given for years to come.

OBITUARY OF THE WAR.

It is only a coincidence that in our obituary column this week occur the names of a member of the Canadian Army Medical Corps, of the Indian Medical Service, of the Royal Army Medical Corps, and of an assistant surgeon of the United States Navy. The individual loss of these men in the prime of life to their respective services and countries cannot now be fully estimated. They were all men of unusual brilliance and enterprise. But their chance association side by side in our obituary column is an example of the astonishing way in which the present war has brought together the medical profession of all English-speaking countries into a community of work and suffering which will, we believe, long outlast the occasion which produced it. From this free interchange of medical thought, and broadening of contemporary medical art and science which it will bring about all over the globe, great good must result.

DUDLEY W. QUEEN, M.D. LOUISVILLE,

ASSISTANT SURGEON, UNITED STATES NAVY.

Dr. D. W. Queen, who died at Queenstown, Ireland, on Nov. 19th at the age of 31 years, was a native of Texas, and graduated from the medical department of the University of Louisville, Kentucky, in 1912. After serving as resident medical officer at the Louisville City Hospital, he settled in private practice at Temple, Texas, where he held an appointment at The King's Daughters' Hospital. On May 5th, 1917, he was commissioned an assistant surgeon in the United States Navy. Surgeon Queen was unmarried.

WALTER LEONARD MACLEAN, M.D. NOVA SCOTIA,

MAJOR, CANADIAN ARMY MEDICAL CORPS.

Major W. L. Maclean, who was recently killed on active service at the age of 32 years, was a native of McLeod, Alberta, and second son of the Rev. J. Maclean, M.A., Ph.D. After taking the first year of an Arts course at the University of Manitoba, his father was transferred to Halifax, N.S., and he then entered the Dalhousie Medical School, graduating in 1908. After a year spent as house surgeon to the Victoria General Hospital at Halifax, he became assistant to the late Dr. R. H. McKeen, surgeon to St. Joseph's Hospital, Glace Bay, Cape Breton, whose large practice among the mining population was taken over when he died in 1912 by his three assistants—Dr. Maclean, Dr. Calder, and Dr. McCuish, whose death at the front was recorded in THE LANCET two weeks ago. Joining the C.A.M.C. in December, 1914, in the following February he came overseas as medical officer to a Canadian Artillery Brigade, and after a few weeks spent in England was sent to France to a Canadian Stationary Hospital, was transferred later to No. 1 Canadian General Hospital, and at the beginning of last year to a casualty clearing station. This hospital had recently been shelled, necessitating its withdrawal to a point further back. It was during this period, while temporarily attached to a British casualty clearing station, that he had just finished operating and was proceeding to the wards at 7 o'clock in the evening, when bombs were dropped upon the hospital from an aeroplane, and he received injuries from which he died within a few hours. One of Major Maclean's senior officers writes: "By his death Canada has lost one who, despite his youth, had accomplished remarkable work. By sheer capacity he rose to be head of the surgical service of a well-known casualty clearing station, and there he worked unremittingly. The pity is that no adequate record remains of his series of operations, more particularly of his results with grave abdominal wounds at the front, results which were very remarkable." Major Maclean leaves a widow, but no children.

AUSTIN EDMUND BASIL CLARKE, M.B., CH.B. ABERD.

MILITARY CROSS,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain A. E. B. Clarke, who was killed in action in France on Nov. 23rd at the age of 25, was elder son of the late Dr. Albert Bleckly Clarke, of Shebbear, North Devon. From Shebbear College he entered the University of Aberdeen, where he joined the O.T.C. and graduated M.B., Ch.B. in 1915. He at once obtained a commission in the R.A.M.C., and in July of the same year went to France as regimental surgeon to the Queen Victoria Rifles. In 1916 he was awarded the Military Cross for gallantry. He met his death from a shell which killed him instantaneously with three other officers. His colonel writes that he loved and was beloved by the men under his care.

Captain Clarke was a good all-round athlete and horseman, and had gained the first prize in a divisional steeplechase a few weeks before his death.

DAVID ARTHUR, B.SC., M.B., CH.B. GLASG.

MILITARY CROSS,

CAPTAIN, INDIAN MEDICAL SERVICE.

Captain D. Arthur, who died on July 31st at the age of 32 while a prisoner of war in Turkey, was youngest son of the late Provost Arthur, of Airdrie. He was educated at the Airdrie Academy and Glasgow University, where he graduated B.Sc. in 1905 and M.B., Ch.B. in 1907. After a short spell of general practice and filling a resident appointment at the Western Infirmary, Glasgow, he passed into the I.M.S. in 1909 and proceeded to India, where he was attached to the 8th Rajputs. A few days before the outbreak of war he had arrived home on a year's leave, but was at once sent back to India, whence he sailed for the Persian Gulf with the first Indian Expeditionary Force to that area. He took part in the landing at Mohamerah and after much arduous service, in the course of which he was twice mentioned in despatches, he went through the early

of Kut-el-Amara. At Ctesiphon he was wounded in the arm, back, and leg, but did not go on the sick list. On the fall of Kut he was taken prisoner, and later was put in medical charge of prisoners working on a section of the Bagdad Railway. While tending these patients he got his hand infected and died four days later at Entelli of septicæmia. While he was a prisoner the award of the Military Cross to him was published. Letters from fellow officers speak of Captain Arthur's social qualities. "Very good at his job and always cheery, he was a man with a great heart, and will be badly missed by all those that are left. In Kut he worked hard, and his cheery optimism and witty stories were invaluable." "Under the worst circumstances he saw a bright side, and always had a smile."

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

We have alluded in a leading article to the organised endeavour of the British Medical Association to support the War Emergency Fund of the Royal Medical Benevolent Fund in a further appeal. This energetic Fund by a first appeal raised £4000, while a second appeal brought a further £10,000. It is desired now to raise at least £30,000 more, and the British Medical Association has invited the secretaries of every division of the Association to make a combined effort towards this end. The War Emergency Fund was instituted to afford assistance to members of the medical profession who, in consequence of having joined the medical service of the Navy or the Army, find themselves involved in difficulties. Many of these men have had to face severe falls in income and to leave home without making adequate arrangements for the maintenance of their practices. There is no doubt of the real need for substantial sums to meet the indicated difficulties, and we have every confidence in the response that will be given by the divisions of the Association.

REGISTERED DENTISTS AND VOLUNTEER TRAINING.

A question has been recently asked in Parliament whether tribunals could, in granting exemption of registered dentists, impose the condition that they should join a Volunteer Training Corps. The answer given was that such a proceeding was not *ultra vires*, but that the condition should not be imposed unless it was clear that the man could spare the time and that his work would be in the national interest. It was also stated that owing to the demand for dental services it would be better, when possible and reasonable, that the imposed condition should take the form of requiring such additional dental service as might be recommended by the Dental Service Committee. The question raises an important principle—namely, whether manpower is or is not to be employed in the best possible way for national needs. The registered dentist of military age has passed through a curriculum which includes a considerable amount of medical and surgical instruction, and it is clear that to attach him to a Volunteer Training Corps as an ordinary infantryman is misapplication of skilled training. The right condition to impose is that suggested in the latter part of the answer—namely, to require of the exempted men additional public dental service. If this is not feasible, then any imposed condition should take the form of attaching him for service either to a military hospital or to the medical section of a Volunteer Training Corps.

VOLUNTARY CONSCRIPTION ON THE RAND.

A report has been presented by the Medical Services Committee appointed by the Witwatersrand branch of the British Medical Association to give effect to the principle of voluntary conscription adopted by the branch. Of the total 143 members of the branch 45 are now on military service, and another 30 had returned after a period of service. Of the 98 members not serving at the moment, a large proportion had offered their services, but with a third of the doctors away the extra burden thrown on those who remain is already considerable. The Director of Medical Services has arranged that, so far as possible, doctors invalided out of the service should replace those who are desirous of serving. As regards the actual numbers, 28 members are classified as unfit for service or cannot be spared; 16 are full-time officers, whose ability to get away depends on their employers or on ability to obtain a locum tenens; 21 are part-time officers, and the cases of 13 are being further considered. Most, if not all, of the other branches of the British Medical Association in South Africa are conducting a voluntary conscription campaign. The committee appeals to public authorities not to make permanent appointments during the war, but to fill them temporarily with men unfit for military service or discharged from such service. It is also urged upon those who manage the benefit societies in connexion with the mines that they should keep open the positions of their medical officers who had gone on active service.

Lieutenant-Colonel A. W. Sheen, who was the first officer in command of the Welsh Hospital at Netley, and who later went out to India in charge of a hospital at Deolali, has been appointed consulting surgeon to the war hospitals in India, with headquarters at Bombay.

THE ROYAL NAVAL HOSPITAL, STONEHOUSE.—Winter Villa, Stonehouse, has been lent to the Admiralty for the duration of the war. It is to be used as a hostel for the V.A.D. nurses who are working at the Royal Naval Hospital, and will be able to provide accommodation for about 70 nurses.

OFFICERS' CONVALESCENT HOME.—A convalescent home for British officers suffering from shell shock and nerve injuries was opened at "Westgate," Beckenham, on Nov. 15th, as a gift from the Dutch residents in this country. The first year's expenditure, amounting to £3000, has been guaranteed, and an appeal for further funds is being issued to Dutch residents in other countries. The honorary treasurer is Mr. J. van Maurik, 21, Bucklersbury, London, E.C.

ORTHOPÆDIC CENTRE FOR THE TREATMENT OF DISABLED SOLDIERS AND SAILORS IN EDINBURGH.—The Ministry of Pensions has now formally approved of the arrangement between the corporation of Edinburgh and the Joint Disablement Committee for South-East Scotland in connexion with the provision of an orthopædic centre at Tynecastle, Edinburgh, for the treatment of disabled soldiers and sailors. Tenders have been received for the erection of the new centre, and estimates amounting in all to £3393 9*s*. 6*d*. were accepted.

FIELD GLASSES FOR AMBULANCE WORK.—There is no doubt that the use of field glasses is a powerful factor in searching out and rescuing men who fall at a distance from the lines. Lady Roberts's appeal for support to her Field Glass Fund will not therefore fall on deaf ears as far as our readers are concerned. 30,000 instruments have been sent out, and the main expense is now in the repairing of glasses that come back for re-issue. Contributions, as well as any field glasses and telescopes that can still be spared, may be sent to the Manager, Lady Roberts's Field Glass Fund, 64, Victoria-street, London, S.W. 1.

COURT-MARTIAL ON AN OFFICER OF THE R.A.M.C.—At Victoria Barracks, Belfast, on Dec. 12th, a public court-martial was held on Captain J. S. Robinson, R.A.M.C., who was charged with neglect of duty because, on receiving a telephone message from the Midland Railway Station, Belfast, to the effect that the railway transport officer wanted him to send an ambulance for a man (a soldier) who was being transferred from Belfast to the hospital at Londonderry, and who was ill and was lying down, he (Captain Robinson) neither sent an ambulance nor went to see the man. For the defence, it was proved that Captain Robinson, when the telephone message came, attended to it—though it was no part of his duty to do so—and told the railway transport officer that if he was not satisfied to give him a ring later, and an ambulance would be sent. He did not consider it necessary to make any report about the matter, as the statement of the railway transport officer was not inconsistent with the diagnosis. The soldier died of acute pancreatitis—this was revealed at the autopsy. The court returned a verdict of "Not guilty," and in ordering the release of Captain Robinson the President congratulated him upon the result of the inquiry.

THE LANCET, VOL. II., 1917: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 29th will be ready early in the New Year. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

UNIVERSITY OF OXFORD.—At examinations for the degree of Bachelor of Medicine, held recently, the following candidates were successful in the subjects indicated:—

FIRST EXAMINATION.

Organic Chemistry.—J. A. Barnett, Corpus Christi; C. C. H. Chavasse, Hertford; C. R. Lane, Pembroke; H. A. Osborne, New College; and I. M. Sidley, Christ Church. Women: N. E. Bodkin and D. J. Collier, Society Oxford Home Students; D. W. Crook and K. M. Hodgkinson, Somerville College; J. Orr-Ewing, Lady Margaret's Hall; and C. M. Ottley, Society Oxford Home Students.

Human Anatomy and Human Physiology.—J. Harris, Jesus; and W. S. Tunbridge, Lincoln.

SECOND EXAMINATION.

Materia Medica and Pharmacology.—F. G. Hobson, New College; H. P. Hodge, non-collegiate; E. G. T. Liddell, Trinity; and W. V. Robinson, New College.

Pathology.—E. H. Cluver, Hertford; F. G. Hobson, New College; C. F. Krige, Hertford; W. V. Robinson, New College; E. A. Thomas, University College; and E. A. Woods, Magdalen.

Forensic Medicine and Public Health.—C. W. W. Armstrong, St. John's; W. Gover and R. T. F. D. Roberts, Balliol; G. K. Stone, Trinity; H. W. Toms, Jesus; B. Tordoff, St. John's; and E. A. Woods, Magdalen.

Medicine, Surgery, and Midwifery.—C. W. W. Armstrong, St. John's; F. B. Dutton, Magdalen; W. Gover, Balliol; R. M. Humphreys, St. John's; R. T. F. D. Roberts, Balliol; and G. K. Stone, Trinity.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on Dec. 13th, Mr. Charters J. Symonds, the Senior Vice-President, being in the chair.—A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that at the recent examination there were 25 candidates, of whom 12 were approved.—A report was read from the Court of Examiners relating to the recent examination for the Fellowship; it stated that there were 13 candidates and that of these only one acquitted himself satisfactorily. The Council resolved to issue a Diploma of Fellow to the successful candidate, Hugh Ernest Griffiths, St. Bartholomew's Hospital. The Diploma of Member was conferred upon Thomas Pomfret Kilner, Manchester University. Licences to practise dentistry were conferred upon the following 22 candidates who have passed the requisite examinations and have complied with the by-laws:—

Kenneth Charles Brough and Malcolm Beverley Burton, Guy's Hospital; Alfred Innes Cox, Middlesex and Royal Dental Hospitals; Peter Jacob Stephanus de Wet, Guy's Hospital; Francis Desmond Donovan, Middlesex and Royal Dental Hospitals; Hyman Fox, Guy's Hospital; Blanche Sutton Gardner, Royal Free and National Dental Hospitals; Philippus Elisa Grobbelaar, Guy's Hospital; Hugh Donald Hoggard, Middlesex and Royal Dental Hospitals; James Ernest Horton, London Hospital; John Christopher Johnson, Hugh Llywelyn Jones, and Felix Reginald Knowler, Guy's Hospital; Stephen Alphonsus McCormack, Middlesex and Royal Dental Hospitals; Georges Maes, Brussels and Royal Dental Hospital; Herbert Myers Marshall, Harry Millett, and Edward Alfred Penney Parker, Guy's Hospital; Ernest George Parkinson, Manchester University; Clarence Norman Pearson, London Hospital; Sydney Kilshaw Rigg, Bristol University; and George Wilshere, Guy's Hospital.

The Senior Vice-President reported that he had attended in the theatre of the College on Nov. 15th at 3 o'clock, and that as the required quorum of 30 was not present he had declared, after the expiration of 15 minutes, that the meeting could not be held.—The Senior Vice-President reported the delivery by Sir John Bland-Sutton on Nov. 8th of the Bradshaw Lecture on "Misplaced and Missing Organs." The best thanks of the Council were given to him for his lecture and he was requested to publish it.—The secretary reported that Corporal Henry Brightwell, R.A.M.C., who was an attendant in the museum from 1900 to 1915, and who enlisted early in 1915, had died of cholera on board H.M. Hospital ship *Devanha* on Nov. 4th. The Council decided to express their condolences to the widow and directed that the deferred allowance standing to the credit of her husband in the books of the College should be paid to her.—Sir Berkeley Moynihan was appointed a member of the Court of Governors of the University of Birmingham for a period of three years in the vacancy occasioned by the retirement of Sir W. Watson Cheyne. Mr. D'Arcy Power was appointed a member of the Court of the University of Bristol in the vacancy occasioned by the expiration of the period of office of Sir Rickman J. Godlee. Mr. W. G. Spencer was appointed a member of the Central Council of District Nursing in the vacancy occasioned by the retirement of Sir Alfred Pearce Gould.—A letter was read from Mr. H. J. Waring reporting the proceedings of the General Medical Council at their recent session. The best thanks of the Council were given to Mr Waring for his services as the representative of the College and they directed that his letter should be entered on the minutes.

ROYAL INSTITUTION OF GREAT BRITAIN.—A series of Christmas lectures, adapted to a juvenile audience and entitled "Our Useful Servants: Magnetism and Electricity," will be delivered by Professor J. A. Fleming, D.Sc., F.R.S., M.R.I., on Thursday, Dec. 27th, and Saturday, Dec. 29th, at 3 o'clock.

READING PATHOLOGICAL SOCIETY.—This society, one of the oldest medical associations in the United Kingdom, has decided *nemine contradicente* to admit women practitioners to membership, thereby reversing the decision arrived at on former occasions when such a proposal was mooted.

LIVINGSTONE COLLEGE.—The annual report of Livingstone College shows that 1500 patients have been admitted since the institution was turned into an auxiliary of the Bethnal Green Military Hospital in August, 1915. The hope is expressed that the lessons gained in solving the problem of emergency hospital training may give fresh stimulus to the elementary medical training for missionary work, which is the normal occupation of the college.

THE ROYAL SANITARY INSTITUTE AND A MINISTRY OF HEALTH.—At a special meeting of the council of the Royal Sanitary Institute (90, Buckingham Palace-road, London, S.W. 1), called to consider the proposals made for the formation of a Ministry of Health, a resolution was passed directing attention to the fact that any scheme affecting so many interests and authorities demands very full consideration, and offering the coöperation of the council of the Institute in the preparation of legislation. As long ago as 1883 the Sanitary Institute had under consideration proposals for collecting all public health work under one Government department.

INFANT WELFARE IN IRELAND.—The sixth of the lectures on infant welfare (the first series to be given in Ireland) was delivered in the Central Public Library, Belfast, on Dec. 11th by Dr. R. J. Johnstone on the Choice and Care of Parents. In presiding, Dr. E. C. Bagge, Medical Commissioner to the Local Government Board for Ireland, spoke of the importance of these lectures, which were given under the auspices of the local authorities in Ireland. He said that he looked forward with high expectations to the new franchise, believing that the women would give a grand impetus to child welfare.

CARE OF DISABLED IN SOUTH-EAST SCOTLAND.—A meeting of the Joint Disablement Committee for South-East Scotland was held recently at the City Chambers, Edinburgh, Bailie Adams presiding. The Joint Committee approved the arrangements for the establishment of Craigend, Liberton, as a hospital for the treatment of neurasthenics. Exception was taken to the provision of the Institutional Committee that it was to be reserved for acute cases, and it was agreed to make a representation on the subject to the institutional Committee. It was also intimated that the Ministry of Pensions had made an application for release from the Army of Dr. R. Cunyngham Brown, Deputy Commissioner of the Board of Control, for the purpose of taking up the position of medical superintendent of the hospital, and the military authorities had agreed to his release. The Institutional Committee have indicated that men will be admitted only on the recommendation of the Medical Board for Neurasthenia presided over by Lieutenant-Colonel Macpherson. The Joint Committee also approved of the scheme for the establishment of an epileptic colony at Muireston, let of which, including mansion house, steading, and land, has been arranged with the Distress Committee of Edinburgh for a period of ten years at £200 per annum.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 12TH.

Physical Capacity of Indian Garrison Troops.

Mr. NIELD asked the Under Secretary for War whether he was aware that considerable differences of opinion existed between the local Indian military authorities and the officers commanding battalions sent out in India for garrison duty to replace troops withdrawn for active service in the field as to the physical capacity of many non-commissioned officers and men in such substituted battalions who were suffering from (*inter alia*) v.d.h., rupture, varicocele, chronic bronchitis, asthma, rheumatism, and frost-bite, to perform in India the ordinary duties of Native garrison battalions or sound and seasoned European troops; and whether any commanding officers had been removed from their command because of their action in limiting the duties of such substituted battalions to work which their physical condition would allow them to perform having regard to the climate.—Mr. MACPHERSON answered: So far as my information goes the answer to both parts of the question is in the negative. I should, however, be glad to receive any information which the honourable gentleman may have in his possession.

Grants to Voluntary Hospitals.

Sir WILLIAM COLLINS asked the Financial Secretary to the War Office whether he was now in a position to state what increases in the scales of grants to voluntary hospitals in respect of treatment of wounded soldiers had been decided upon.—Mr. FORSTER: The maximum grant for Class A Auxiliary Hospitals has been raised from 3*s.* to 3*s.* 3*d.*, and for Class B from 2*s.* to 2*s.* 6*d.*

British and Turkish Prisoners.

Answering Mr. HUME-WILLIAMS, Mr. JAMES HOPE (representing the War Prisoners Department) stated that the conference in Switzerland between Turkish and British representatives with reference to a suggested exchange of prisoners was now sitting, and he trusted that a satisfactory solution might be arrived at. He was not, however, yet in a position to make any statement on the subject.

THURSDAY, DEC. 13TH.

Milk for Infants.

Mr. WHITEHOUSE asked the Parliamentary Secretary to the Ministry of Food whether, in arranging for the more equitable distribution of milk, he had considered the numerous cases where it was necessary to feed young infants wholly upon cow's milk; and whether he could state the approximate cost, at present rates, of the milk requisite for an infant who had to be thus fed.—Mr. CLYNES said in reply: Food control committees are empowered to give priority to any consumers in their area. The cost of the milk required for a child depends upon the age of the child and upon the sale price of milk, which is fixed by the local food control committees and varies at the present time from 5*d.* to 8*d.* a quart.

Middlesex Practitioners and Invalided Soldiers.

Major NEWMAN asked the representative of the National Insurance Commissioners whether he could state the number of Middlesex panel practitioners who had notified their respective Insurance Committees that they were not prepared to accept invalided seamen, marines, and soldiers on their lists under the terms of the new regulations.—Sir EDWIN CORNWALL answered: I am not aware of any medical practitioner in Middlesex having refused to render treatment in any such case. I may add that the regulations in question are framed in accordance with the express desires of authorities representative of the medical practitioners concerned, and that events subsequent to their issue have shown that the regulations are, in fact, acceptable to the great majority of such practitioners.

Transfer of Prisoners to Holland.

Mr. HUME-WILLIAMS asked the representative of the War Prisoners Department whether he could make a statement with reference to the expected arrival of British prisoners in Holland under the recent agreement entered into with Germany at The Hague.—Mr. JAMES HOPE said in reply: We have just heard that it is proposed to effect the first transfer of British prisoners to Holland on Jan. 2nd. We have no reason to suppose that any further obstacle will arise.

Mr. BUTCHER: Will the first transfer be of civilian prisoners, and will that be followed by military prisoners?—Mr. HOPE: I understand the first transfer is to be between civilians and a certain number of wounded and other officers.

Sufferers from Leprosy.

Colonel YATE asked the President of the Local Government Board how many cases of leprosy there were in this country; and whether steps were being taken to segregate persons suffering from leprosy and to provide for their treatment and maintenance.—Mr. STEPHEN WALSH (Parliamentary Secretary to the Local Government Board) replied: My right honourable friend has no exact information, but he is informed that there are only a few cases of leprosy in the country, and, so far as he is aware, the disease is not spreading here. My right honourable friend is advised that the infectivity of the disease is very limited, and that measures for the compulsory segregation of persons suffering from leprosy in this country would not be justified at present. He understands that valuable work in the treatment and maintenance of such cases is being done by private funds.

Colonel YATE: Would it not be advisable for the Government to give some help to those charitable institutions?

Mr. TENNANT: Is not this one of the notifiable diseases?

Mr. WALSH: Yes, I think so, but I am not quite certain on the point. There are three or four extremely valuable organisations dealing with this work, and so far as the Department is aware, there is no special need of Government assistance. The work is being extremely well done, and there are very few cases indeed. Should the necessity for Government assistance arise, it will be a matter for future consideration.

Colonel YATE: Would it not be advisable that these men should be compulsorily put into these charitable institutions?

Sir WILLIAM COLLINS: Is there not high authority for the opinion that while leprosy may be regarded as an inoculable disease, it is not in the ordinary sense of the word communicable?

Mr. WALSH: That is already in the answer. We are advised that the infectivity of the disease is very limited.

Welfare of the Blind in Ireland.

Answering Mr. P. MEEHAN, Mr. DUKE, Chief Secretary for Ireland, stated that he was in communication with the President of the Local Government Board with reference to the appointment of an advisory committee in Ireland in connexion with carrying out the recommendations of the Departmental Committee on the Welfare of the Blind.

BOOKS, ETC., RECEIVED.

BALE, JOHN, SONS, AND DANIELSSON, London.
Laboratory Studies in Tropical Medicine. By C. W. Daniels, M.B. Camb., F.R.C.P. Lond., and H. B. Newham, M.D. Dub., D.T.M. & H. Camb. Fourth edition, thoroughly revised. 21*s.* net.

Appointment.

MODY, G. T., M.B., B.S., has been appointed House Surgeon to the Royal Eye Hospital, Southwark, London.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).
When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BARNSLEY, BECKETT HOSPITAL.—Second Female House Surgeon. Salary £225 per annum, with board, &c.
BEDFORD COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £174 10s. per annum. Also House Physicians. Salary £152 10s. per annum, with board, &c.
BIRKENHEAD, BOROUGH HOSPITAL.—Junior House Surgeon. Salary £170 per annum, with board, &c.
BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon. Salary £200 per annum, with board, &c.
BRISTOL EYE HOSPITAL.—House Surgeon, unmarried. Salary £120 per annum, with board, &c.
BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.
CHICHESTER, GRAYLINGWELL WAR HOSPITAL.—Resident Medical Officer. Salary £1 per diem, with board, &c.
EAST HAM EDUCATION COMMITTEE.—Female Temporary Assistant School Medical Officer. Salary £350 per annum.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Two House Surgeons. Salary at rate of £100 per annum, with board, &c.
KINGSTON-UPON-HULL, CITY AND COUNTY OF.—Resident Medical Officer. Salary £400 per annum, with board, &c.
MANCHESTER ROYAL INFIRMARY (CENTRAL BRANCH).—Resident Surgical Officer. Salary £200 per annum.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Temporary Assistant Physician. Salary at rate of £12 10s. for one attendance per week.
ROCHESTER, KENT, ST. BARTHOLOMEW'S HOSPITAL.—Senior Resident House Surgeon. Salary at rate of £300 per annum, with board, &c.
SALOP COUNTY COUNCIL.—Temporary Assistant School Medical Officer. Salary at rate of £400 per annum.
UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Temporary Lecturer in Physiological Chemistry. Salary at rate of £200 per annum.
WALSALL AND DISTRICT HOSPITAL.—Female Senior House Surgeon. Salary £250 per annum, with board, &c.

Births, Marriages, and Deaths.

BIRTHS.

BAYLEY.—On Dec. 7th, at Albert-road, Regent's Park, the wife of Captain H. H. R. Bayley, R.A.M.C., of a daughter.
KEELING.—On Dec. 16th, at Attleborough, Norfolk, the wife of G. S. Keeling, M.D., of a son.
MACFIE.—On Dec. 13th, at Newcastle-on-Tyne, the wife of Captain R. Bute Macfie, R.A.M.C., of a daughter.
MARTYN.—On Dec. 10th, at Netherclay House, Bishops Hull, near Taunton, the wife of Captain V. C. Martyn, M.C., R.A.M.C., of a son.

MARRIAGES.

GRIFFITH—RUCK.—On Dec. 6th, at Holy Trinity Church, Corris, Major Alexander Hill Griffith, R.A.M.C. (T.), to Mary Ursula, second daughter of Lieutenant-Colonel A. A. Ruck, late 8th The King's Regiment, and Mrs. Ruck, of Esgair, Pantperthog, Merioneth.

DEATHS.

ANDERSON.—On Dec. 17th, at Alde House, Aldeburgh, Suffolk, Elizabeth Garrett Anderson, M.D., aged 81. Funeral Friday, 21st Dec., 2.30 P.M., Aldeburgh. Memorial service at Christ Church, Endell-street (Military Hospital), on Saturday, 22nd Dec., at 11 A.M. No flowers by request.
EDMOND.—On Dec. 1st, killed in action, John Adamson Edmond, M.B., B.S., M.R.C.S., L.R.C.P., Captain, R.A.M.C.
GRIFFITHS.—On Nov. 30th, killed in action, John Neville Griffiths, M.B., D.P.H., temporary Captain, R.A.M.C., aged 36.
SHARLAND.—On Dec. 14th, Dr. Arthur Sharland, Charleville-circus, Sydenham, in his 69th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

BOOKS OF REFERENCE.

THE aim of Sir Henry Burdett's well-known compilation, *Burdett's Hospitals and Charities, 1917* (London: The Scientific Press, Limited. Pp. 1074. Price 12s. 6d. net, is given on the title-page as follows: "Being the year book of philanthropy and the hospital annual containing a review of the position and requirements, and chapters on the management, review, and cost of the charities. An exhaustive record of hospital work for the year. It will also be found to be the most useful and reliable guide to British, American, and colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, consumption sanatoria, religious and benevolent institutions, and dispensaries." And we reproduce it here because the compiler, who is now completing the fiftieth year of his work for hospitals, is seeking someone technically and otherwise competent and willing to coöperate in editing the year-book. We congratulate Sir Henry Burdett upon his twenty-eighth edition, delayed as it has been by the grave difficulty of collecting reliable statistics in war time, and we wish him well in finding a worthy successor.

A CURIOUS ACTION OF MERCURY ON ALUMINIUM.

To the Editor of THE LANCET.

SIR,—The enclosed letter which I received from Dr. G. T. Western may be of interest. It gives more complete information on the subject than I have found elsewhere. The authorities seem to be agreed that moisture is an essential part of the reaction, and the formula given by Dr. Western seems plain enough:—

$$2Al + Hg + 3H_2O = Al_2O_3 + 6H + Hg.$$

Presumably when corrosive sublimate is used in place of metallic mercury the formula would read:—

$$2Al + 3HgCl_2 + 3H_2O = Al_2O_3 + 6HCl + 3Hg,$$

hydrochloric acid being formed in place of pure hydrogen, and it may be that the irritating quality noticed by me is due to the fumes of nascent HCl. It is curious that both Captain M. H. Fleming (THE LANCET, Dec. 15th) and myself thought that the reaction took place better in the absence of moisture, and I at any rate have noticed no sign of metallic mercury in the residue, the aluminium being apparently eaten away, as it might be by a corrosive acid.

I am, Sir, yours faithfully,
Bromsgrove, Dec. 16th, 1917. H. CAMERON KIDD.

[ENCLOSURE.]

29, Nottingham-place, W. 1, Nov. 28th, 1917.

DEAR SIR,—The phenomenon you describe in THE LANCET interested me, in so far as I also observed it some years ago by chance in a similar manner to you. At the time I investigated the matter and found that the mercury forms an amalgam with the aluminium. In the presence of moisture katalytic action then takes place thus:—

$$2Al + Hg + 3H_2O = Al_2O_3 + 6H + Hg.$$

If you allow the action to take place in water under an inverted tube you will collect pure hydrogen, the Hg going on to the next layer of aluminium, and the process continues until the aluminium is completely eaten away, and whereas you commenced with $HgCl_2$ you finish with a small bead of metallic mercury. You may equally well commence the process with metallic mercury. This phenomenon was exploited five or six years ago in a toy—a man's face stamped out of sheet aluminium and painted except the chin and eyebrows. A small pencil was supplied made of a mercury amalgam. This was then rubbed on the chin and eyebrows, and the beard and eyebrows were made to grow.—I remain, yours faithfully.
Dr. H. Cameron Kidd. G. T. WESTERN.

ANAPHYLACTIC DRUG REACTIONS.

AT Professor Lewandowsky's dermatological clinic in Berlin Dr. W. Lutz has shown good reason for thinking that the febrile reaction, sometimes accompanied by skin eruption, following on a second intravenous injection of salvarsan or of quinine, is really an allergic reaction of the same nature as so-called serum disease. His reasons are set out in the *Correspond.-bl. f. Schw. Ärzte* for Dec. 1st.

SLAUGHTER-HOUSE REFORM.

WE have often urged the importance of applying a sound standard of sanitation to slaughter-houses, and at a time when our meat-supply is curtailed the swift and wholesome preparation of carcasses is doubly important. The best and most humane methods of killing animals are dealt with in a pamphlet compiled by Mr. S. M. Dodington for the Council of Justice to Animals (21A, Savile-row, London, W. 1. Price 1s.). It sets out in tabular form the progress of the movement in favour of more humane methods in killing animals used for food in the northern countries of Europe and in parts of England. A general review of slaughter-house hygiene, including references to many of the articles which have appeared in our columns, will be found in THE LANCET, 1909, ii., 495.

DEATH-RATE IN THE FIJI ISLANDS.

THE report for 1916 of the medical department of the Fiji Legislative Council, signed by the chief medical officer, Dr. G.W. A. Lynch, shows the same striking decrease in the death-rate of all sections of the population which is apparent in other parts of the Empire. In a scattered colony where registration is not yet perfect the figures as given are not claimed to possess absolute accuracy; but the steady decline in the yearly rates since 1912 is encouraging, and the present rate is a very low one for a tropical country.

Race.	1912. Per 1000.	1915. Per 1000.	1916. Per 1000.
Europeans	10·5	9·1	7·9
Fijians	31·3	28·3	25·1
Indians	16 5	10·6	8·7
All races	24·6	20·4	17·5

It should be added that the birth-rate has also declined, although not in the same ratio.

THE STUDY OF ENVIRONMENT.

OPPORTUNITIES in the past for the study of the social factor in disease have not been too abundant for the medical student, and the Student Christian Movement is proposing to supply the need in a Social Study School for Medical Students, to be held at Mansfield House, Canning Town, London, E., from Jan. 4th–7th next. The express purpose of the school is to put before medical students the extent and gravity of the problems of poverty, their relations to one another, and effect on health and character. Visits to factories, docks, and street markets have been arranged, and addresses on various social subjects will be given by Mr. P. I. Watkin, Dr. Jane Walker, Mr. Harry Roberts, Dr. Sidney Davies, and Dr. S. R. Gloyne. A charge of £1 5*s*. covers board and lodging at Mansfield House, and application for registration should be made to Mr. Hugh Martin, M.A., Annandale, North End-road, London, N.W. 3.

MEDICAL INVENTORS.

Dr. S. D. Clippingdale writes: The interesting list of medical inventors you give in your issue of Dec. 15th (p. 916) is capable of expansion:—

Peter Chamberlen, inventor of the midwifery forceps, who had a craze for inventing, produced the following: (1) carriages to go without wheels; (2) an apparatus for navigating vessels in a straight line in all winds; (3) a form of printing which would "represent to the eye what sound does to the ear"; (4) a reformed orthography of the English language.

Dr. Timothy Bright, in 1588, invented shorthand.

Sir William Petty, Charles II.'s physician, invented a boat with two keels, an invention which excited the risibility of both the king and Pepys the diarist. N.B.—It was Petty's daughter who, by marrying into the Lansdowne family, brought into that family the only wisdom it ever possessed (according to the family historian, Lord Edmund Fitz-Maurice).

Dr. John Allen, of Bridgwater, obtained in 1730 letters-patent for three inventions—viz., (1) a method for navigating a vessel in a calm, (2) an engine for raising water by means of fire, (3) a new method of drying malt. He also invented a chariot upon steel springs which could travel "sixty miles a day without being overturned."

Dr. David Bridges, of Hull, invented (*circa* 1780) spermacetti candles.

Dr. Neil Arnott, about 1832, invented the water-bed, a ventilating chimney, and a smokeless grate.

Dr. Battie, of Marlow, introduced traction of barges by horses instead of by men. In building his own house, however, Dr. Battie forgot the staircase!

Dr. Richard Gatling, in 1861, invented the Gatling gun.

Dr. Joseph Ignatius Guillotin is said to have invented the decapitating instrument which bears his name.

Lastly, "*Francis Moore, Physician*," was the orginator of that prescient periodical, "Old Moore's Almanack."

COMMENDABLE HYGIENE.

A WORD of acknowledgment is due to the authorities of the London Underground system of railways for their promptitude in making their stations clean and sweet after use as air-raid shelter.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

TO SUBSCRIBERS IN THE UNITED STATES.

Messrs. Wm. Wood and Co., of New York, are relinquishing their Agency for the supply of THE LANCET in the United States at the end of the present year. The Manager of THE LANCET will be pleased to supply copies direct from the London Office to subscribers in the United States at the strictly prepaid rate of $8 for twelve months. Subscriptions may commence at any time. Drafts and Money Orders should be made payable to the Manager, Mr. CHARLES GOOD, 1, Bedford-street, Strand, London, W.C. 2, England.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

HUMPHREYS LTD., Knightsbridge, London, S.W.7.

Contractors to the Admiralty, War Office, Australian, N.Z., Canadian and American Governments, &c., &c.

29

THE INTERNATIONAL CONGRESS OF MEDICINE held in London in 1913, represented practically the entire Medical Profession of the world.

The Committee awarded a Gold Medal to VITAFER—as all-British then as it is to-day—"for its excellence as a tonic food."

This serves to emphasise that VITAFER is not to be compared with the many so-called tonic foods hurriedly marketed to replace the German existing tonic foods. VITAFER was introduced as an improvement three years before the war. VITAFER IS A MORE COMPLETE AND BETTER BALANCED FOOD.

Vitafer

The All-British Tonic Food

A Captain in the R.A.M.C. writes:

"I have used your preparation VITAFER in cases where a nourishing light diet was desirable and found it to answer its purpose well. It is a convenient and palatable article of light diet."

Sole Manufacturers:

SOUTHALL BROS. & BARCLAY, Ltd., Lower Priory, Birmingham.

Doctor's sample and full particulars of Vitafer also post free on request.

"Science is, I believe, nothing but trained and organized common-sense, differing from the latter only as a veteran may differ from a raw recruit: and its methods differ from those of common-sense only so far as the Guardsman's cut and thrust differ from the manner in which a savage wields his club."

Professor Huxley.

The Basis of Science

BOOTS PURE DRUG COMPANY LIMITED wish to draw the attention of the medical profession to the following seven scientific preparations. Practitioners who endeavour to keep abreast of the times will find these modern antiseptics of superlative value in general practice.

CHLORAMINE-T

(p-toluene-sodium-sulphochloramide).

Dakin's ideal antiseptic, of wide applicability in medicine and surgery.

In bottles of 1oz., 1/2; 4oz., 3/6; 1lb., 12/6

CHLORAMINE-T GAUZE

In two strengths, containing approximately 5% and 35% Chloramine-T. (5% supplied unless otherwise specified). This should be fixed dry and subsequently moistened, if necessary, when in position.

In sealed packages only, price 1/- per package.

PROFLAVINE

(3·6 diamino-acridine-sulphate).

The improved Flavine derivative.

Equal in antiseptic powers to *Acriflavine*, and in important respects superior, being markedly less toxic and less irritating. Proflavine, being less costly to manufacture, can be sold at a substantially lower price than Acriflavine.

5 gram bottle, 1/4; 20 gram bottle, 5/-

TABLETS OF CHLORAMINE-T

One tablet dissolved in two ounces of water makes a one per cent. solution.

Bottles of 50, 8·75 grain tablets, 2/-
" " 100, " " " 3/9

One tablet dissolved in ten ounces of water makes a one per cent. solution.

Bottles of 12, 43·75 grain tablets, 1/10

CHLORAMINE-T CREAM

Containing approximately one per cent. Chloramine-T. Described and investigated under the name of Chloramine Paste by Vincent Daufresne, Carrel, Hartmann and others, in the *Journal of Experimental Medicine*, 1917.

In Pots. Trial size, 9d.; large size, 2/6.

TABLETS OF PROFLAVINE

(with sodium chloride).

One tablet dissolved in four fluid ounces sterile water makes 1:1000 Proflavine in normal saline.

Bottles of 100 tablets, 3/6

HALAZONE TABLETS.

DAKIN'S NEW WATER DISINFECTANT.
Vide B.M.J., May, 1917.

The action of Halazone is positive, and may be relied upon for crudest waters. Each tablet is sufficient to sterilize one quart of contaminated water, but in cases of extreme contamination a second tablet may be necessary. Halazone is invaluable for those on active service overseas, more particularly in hot climates.

Bottles of 100 tablets, 6d.

Supplies are available for prescription service on application through any of the branches of BOOTS THE CHEMISTS.

Boots Pure Drug Company Limited

MANUFACTURING CHEMISTS AND MAKERS OF FINE CHEMICALS.

Head Offices: Station Street, Nottingham. JESSE BOOT, Managing Director.

PHYSIOLOGICALLY TESTED DRUGS.

Owing to the absence of any adequate Chemical tests for certain very important Drugs, notably ERGOT, CANNABIS INDICA, CONVALLARIA, MAJALIS, DIGITALIS, SQUILL, and STROPHANTHUS, we are submitting these for physiological examination by one of the first experts in the Country, and can guarantee our preparations of them to be of

FULL THERAPEUTIC ACTIVITY.

Battley's Solution of Opium.

Liquor Opii Sedativus

(BATTLEY)

THE OLDEST and still THE BEST Hypnotic and Sedative.

Advantages:

¶ May be given with the greatest safety, being pure and free from harmful matter.

¶ No disagreeable after-effects follow its use.

¶ Never varies in strength.

The *Medical Annual* writes:

"**Battley's Solution of Opium** is a common word in the Practitioner's vocabulary. It has gained its reputation by its intrinsic value as a remedy which contains all that is sedative and anodyne in opium without its resinous constituents, which are, therapeutically speaking, impurities."

Strength—Twice that of Tinctura Opii B.P. Usual Dose—5 to 15 minims.

Issued in 2 oz., 4 oz., 8 oz. and 1 lb. bottles.

NOTE.—We do not guarantee our preparations unless in original bottles with the autograph of Richard Battley over each cork and on the label, without which none is genuine.

Sole Manufacturers:

BATTLEY & WATTS, 18 Wellclose Sq., London, E.

Telegraphic Address: "Sedative, London." *Telephone:* Central 2183.

PAGE NOT AVAILABLE

LISTERINE

A trustworthy, unirritating solution composed of volatile and non-volatile antiseptics; extensively and satisfactorily employed in dilution up to 25% as a wet dressing for surgical and accidental wounds.

LISTERINE

Suitably diluted, applied by injection, douche or spray, often serves a useful purpose in catarrhs and conditions involving hyper-secretion from mucous surfaces. It is an efficient deodorizer.

LISTERINE

On account of its boric and benzoic acid constituents, forms a suitable lotion in dermatitis following vaccination. In various cutaneous disorders its use allays excessive itching or irritation, and promotes cleanliness while exercising its antiseptic effect.

Descriptive literature on request.

THE BURBERRY

The Super-Weatherproof

REPRESENTS the most economical and distinguished form of protection in out-door Dress for war-time.

THE BURBERRY, by its efficient resistance to rain and cold winds, ensures comfort and security under conditions entailing prolonged exposure to chill and damp.

THE BURBERRY, by faultless natural ventilation, entirely avoids the vitiated heat of macintosh or rubber-lined coats.

THE BURBERRY is airylight and gives a splendid sense of freedom, whilst its hygienic warmth in severe weather proves invaluable for maintaining health and comfort.

Patterns, Prices, and Catalogue sent on application.

BURBERRYS' CLEANING WORKS.
Men's and Women's Dress Cleaned and Dyed by the most up to-date process. Weatherproof garments cleaned and reproofed by Burberry processes. Moderate charges. Price list sent on request.

BURBERRYS' BASINGSTOKE HOUSE treats direct commissions from Doctors as approval orders*—i.e., *replaces with its own cheque returned non-approved garment.

Every Burberry Garment bears a Burberry Label

Write to-day for full particulars—

SINGER & CO., LTD., COVENTRY

MINUTES MEAN MONEY WHEN YOU LEAVE YOUR ENGINE RUNNING.

From an economical point of view the Brolt Electric Starter is worth consideration as the engine can be stopped and started whenever a halt is made, thus saving fuel and oil, and reducing wear and tear of engine and chassis. The pressure of a switch is all that is necessary to positively start the engine every time—THE POSITIVE DRIVE NEVER FAILS. The BROLT Starter is British-made—British in quality—British made in reliability. Can be installed on practically any vehicle.

BLENOSAN
CAPSULES

As a routine
treatment for

GENITO-URINARY CONDITIONS.

BLENOSAN is a mixture of the finest East India Santal Oil with a specially prepared fluid extract of Kava-Kava. It is presented in the form of accurately-measured Capsules, and affords an ideal medicament for the treatment of all inflammatory conditions of the urethra.

BLENOSAN is an improvement upon the ordinary Santal, and the full proportion of the alpha resin of Kava-Kava ensures all the anæsthetic and diuretic properties of the root in a standardised and dependable form.

BLENOSAN CAPSULES consequently are indicated in all pathological conditions which affect the genito-urinary system, including acute Cystitis, Vaginitis, and Leucorrhœa, and where intense hyperæmia and swelling of the mucous membrane give rise to a diminution of the urinary canal.

BLENOSAN CAPSULES are well adapted for the continuous and systematic treatment of such cases, and are being used with excellent results by many of the most experienced and successful Physicians.

BLENOSAN CAPSULES can be prescribed for a course of treatment extending over two or three weeks.

PENDYFFRYN HALL SANATORIUM

(NORDRACH-IN-WALES.)

Physicians: Dr. G. M. DOBSON and Dr. GERATY.

FOR THE OPEN-AIR AND INOCULATION TREATMENT OF ALL FORMS OF TUBERCULOSIS.

One of the first Sanatoria opened in the United Kingdom to carry out the treatment as practised at Nordrach. Carefully graduated walks rise through pine, gorse, and heather to a height of over 1000 feet above sea level, commanding extensive views of both sea and mountains. Sheltered from E. and N.E. winds. Climate mild and bracing. Small rainfall. Large average of sunshine. There are over five miles of walks in the private grounds. Rooms heated by hot-water radiators and lit by electric light.

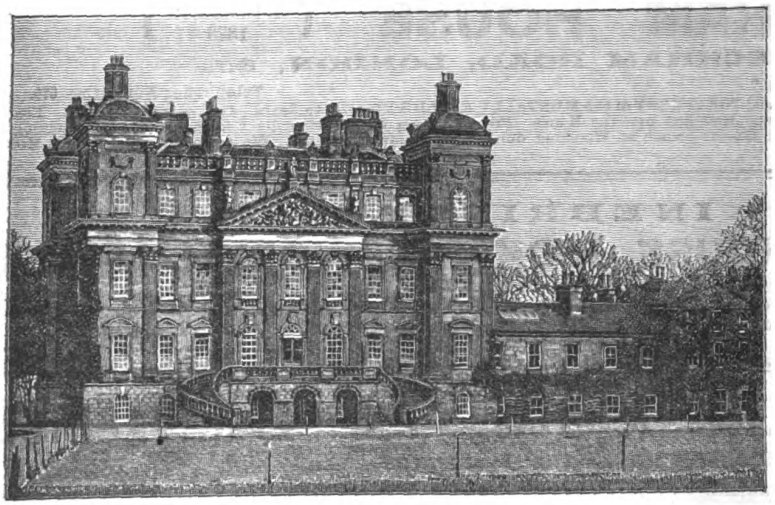
Telegrams: Pendyffryn; and Telephone: 20 Penmaenmawr. Apply, Secretary, Pendyffryn Hall, Penmaenmawr, North Wales.

MATLOCK SANATORIUM

Situated on the edge of the mountain limestone area of Derbyshire, over 700 feet above sea-level. The buildings face south and command beautiful views, while on the north and east they are sheltered by lofty hills. The surrounding country is well known for its great beauty and interest. The climate is dry and bracing. The buildings are lighted by electricity and heated by radiators.

Treatment is carried out on modern lines, all special methods being available in suitable cases. A new X-ray apparatus has been installed, and there is a complete equipment for the carrying out of up-to date methods in all Tubercular and other Pulmonary cases.

For particulars apply to FREDERICK KINCAID, M.R.C.S., L.R.C.P., Medical Superintendent, Matlock Sanatorium, Matlock, Derbyshire. Telephone and Telegraph: SANATORIUM, MATLOCK 22.



VALE OF CLWYD SANATORIUM

This Sanatorium (opened 1901) is established for the Treatment of Tuberculosis as carried out by Dr. OTTO WALTHER of Nordrach. It is situated in the midst of a large area of park-land, at a height of 450 feet above the sea-level, on the western slopes of mountains rising to over 1800 feet, which protect it from North and East winds and provide many miles of carefully graduated uphill walks—similar in character and extent to those at Nordrach.

Small rainfall. Porous subsoil. Large amount of sunshine. Electric Lighting and Hot Water Radiators in each room.

The physician himself was a patient at Nordrach.

For particulars, apply to GEORGE A. CRACE-CALVERT, M.B., &c., Llanbedr Hall, Ruthin, North Wales

FOR THE GENERAL PRACTITIONER.

Clinical Surgical Diagnosis for Students and PRACTITIONERS. Containing a Chapter on **"Some General Diagnostic Problems in connection with the Military Surgery of the Limbs."** By Professor F. DE QUERVAIN, Director of the Surgical Clinic, University of Basle. Translated by J. SNOWMAN, M.D. 862 pp., with 604 Illustrations and 5 Coloured Plates. Second English Edition. Royal 8vo. Price **35s.** net. Postage: inland, 7d., abroad 2s.

"The illustrations ..... are all admirably reproduced. The arrangement of the subjects is from the head to the heel. ..... The book is thus easy to consult, and is particularly suitable for the general practitioner, as it emphasizes those features which are to be noted by clinical observation."—PROCEED. ROY. SOC. OF MED.

SAUNDERS' BOOKS

Recently Issued

DISEASES OF THE EYE

Eighth Edition

By G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology, University of Pennsylvania. Octavo of 764 pages, with 386 illustrations and 7 coloured plates.
Cloth, 25s. net.

"Its outstanding merit is the abundant reference to all the most valuable contributions to the literature of the subject in recent years, and Dr. de Schweinitz succeeds in incorporating these details without marring the general perspective—no easy task. ..... We can cordially recommend the book as belonging to the small group of the very best text-books on ophthalmology."
—THE LANCET.

Eighth Edition

NERVOUS AND MENTAL

Revised and Enlarged

By ARCHIBALD CHURCH, M.D., of Chicago; and FREDERICK PETERSON, M.D., of New York. Octavo of 840 pages, with 350 illustrations. Cloth, 21s. net.

"It probably forms the best text-book exposition of this subject of our day for the busy practitioner ..... the chapter on idiocy and imbecility is undoubtedly the best that has been given us in any work of recent date upon mental diseases."—JOURNAL OF NERVOUS AND MENTAL DISEASES.

Eighth Edition

TREATMENT OF FRACTURES

Beautifully Illustrated

By CHARLES L. SCUDDER, M.D., Surgeon to the Massachusetts General Hospital, Boston. Octavo of 735 pages, with 1057 original illustrations. Cloth, 25s. net.

"Is one of the best of modern works on the subject, and with its full and lucid teaching, supplemented by an abundance of excellent illustrations, will be found a useful guide in the management of this class of injuries."—BRITISH MEDICAL JOURNAL.

Recently Issued

STOMACH, INTESTINES & PANCREAS

New (3rd) Edition

By ROBERT COLEMAN KEMP, M.D., Professor of Gastro-Intestinal Diseases, New York School of Clinical Medicine. Octavo of 1096 pages, with 428 illustrations.
Cloth, 30s. net.

"The writer's intention has been to provide a practical reference book for general practitioners, and in this object he has succeeded. ..... We have pleasure accordingly in commending it to our readers."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

Fifth Edition

GENERAL BACTERIOLOGY

Thoroughly Revised

By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago. Octavo of 647 pages, illustrated. Cloth, 15s. net.

"The popularity of the book is no doubt due to its comprehensive nature and general excellence."

PHILIP TURNER, M.B., M.S.
W. HALE WHITE, M.D., F.R.C.P.

This work aims at being of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain. It covers the whole ground of Medicine, Surgery, Gynæcology, Ophthalmology, Dermatology, and Neurology.

It is a work upon differential diagnosis in that it discusses the methods of distinguishing between the various diseases in which each individual symptom may be observed. The body of the book deals with *Symptoms*, while the General Index, containing some 45,000 references, gathers these together under the various *Diseases* in which they occur.

The second edition was exhausted within nine months of issue, and a third is now issued.

"The new edition is an improvement in many ways on the old, and has been re-cast on ampler lines, with a large number of new illustrations and coloured plates. Having read most of the articles in the book, we have no hesitation in saying that it should be in the hands of all practitioners and senior students. . . . The publisher is to be congratulated upon the printing of the book and its illustrations, perhaps most of all upon the excellence of the many coloured plates; they could not be better, and do great credit to British colour printing."—BRIT. MED. JOUR.

"The first edition of this stately volume has been exhausted within three years. ..... The editor has added new articles, revised old ones, and nearly doubled the number of illustrations. These are not only excellently reproduced, but deal with real difficulties in diagnosis."—LANCET.

"Beyond question a *tour de force*, and reflects the highest credit upon all concerned in its production. The most remarkable feature in the book is its full index ..... an essential part of the scheme ..... will be found a friend in need at all times. ..... We are extremely glad as well to have it made abundantly evident that the finest productions from overseas can be left far behind on every point by those brought forth in this country."—PRACT.

"The volume is a notable contribution to modern medicine ..... an immense amount of valuable information. ..... The illustrations are remarkably good, especially the coloured ones, which in other books often are remarkably bad."—THERAP. GAZETTE.

"It is not difficult to understand why this work has been twice reprinted since 1912, and that a second edition has now been called for. It satisfactorily meets a want which every practitioner experiences almost daily."—EDIN. MED. JOUR.

"Science is, I believe, nothing but trained and organized common-sense, differing from the latter only as a veteran may differ from a raw recruit; and its methods differ from those of common-sense only so far as the Guardsman's cut and thrust differ from the manner in which a savage wields his club."

Professor Huxley.

The Basis of Science

BOOTS PURE DRUG COMPANY LIMITED wish to draw the attention of the medical profession to the following seven scientific preparations. Practitioners who endeavour to keep abreast of the times will find these modern antiseptics of superlative value in general practice.

CHLORAMINE-T

(p-toluene-sodium-sulphochloramide).

Dakin's ideal antiseptic, of wide applicability in medicine and surgery.

In bottles of 1oz., 1/2; 4oz., 3/6; 1lb., 12/6

CHLORAMINE-T GAUZE

In two strengths, containing approximately 5% and 35% Chloramine-T. (5% supplied unless otherwise specified). This should be fixed dry and subsequently moistened, if necessary, when in position.

In sealed packages only, price 1/- per package.

PROFLAVINE

(3·6 diamino-acridine-sulphate).

The improved Flavine derivative.

Equal in antiseptic powers to *Acriflavine*, and in important respects superior, being markedly less toxic and less irritating. Proflavine, being less costly to manufacture, can be sold at a substantially lower price than Acriflavine.

5 gram bottle, 1/4; 20 gram bottle, 5/-

TABLETS OF CHLORAMINE-T

One tablet dissolved in two ounces of water makes a one per cent. solution.

Bottles of 50, 8·75 grain tablets, 2/-
" " 100, " " " 3/9

One tablet dissolved in ten ounces of water makes a one per cent. solution.

Bottles of 12, 43·75 grain tablets, 1/10

CHLORAMINE-T CREAM

Containing approximately one per cent. Chloramine-T. Described and investigated under the name of Chloramine Paste by Vincent Daufresne, Carrel, Hartmann and others, in the *Journal of Experimental Medicine*, 1917.

In Pots. Trial size, 9d.; large size, 2/6.

TABLETS OF PROFLAVINE

(with sodium chloride).

One tablet dissolved in four fluid ounces sterile water makes 1:1000 Proflavine in normal saline.

Bottles of 100 tablets, 3/6

HALAZONE TABLETS.

DAKIN'S NEW WATER DISINFECTANT.
Vide B.M.J., May, 1917.

The action of Halazone is positive, and may be relied upon for crudest waters. Each tablet is sufficient to sterilize one quart of contaminated water, but in cases of extreme contamination a second tablet may be necessary. Halazone is invaluable for those on active service overseas, more particularly in hot climates.

Bottles of 100 tablets, 6d.

Supplies are available for prescription service on application through any of the branches of BOOTS THE CHEMISTS.

Powerful Urinary Antiseptic.

Gonorrhœa, Cystitis, Prostatitis, Catarrh of the Bladder, Renal Tuberculosis, Hypertrophy of the Prostate, and all Diseases affecting the Urinary System.

Acute Conditions: 16 capsules daily.
Chronic Conditions: 6 capsules daily.

PRICE 5/- and 11/- per box.

GYRALDOSE.

Powerful Antiseptic for Local Gynæcological Use.

RELIABLE. NON-INJURIOUS. NON-STAINING.

Leucorrhœa, Metritis, Salpingo-ovaritis, Vaginal Discharges, &c.

Prophylactic and Hygienic Use: One teaspoonful to a quart of warm water, once or twice daily. *Curative Purposes:* Two to three teaspoonfuls to a quart of hot water, twice daily, or oftener if necessary.

PRICE 4/- per box.

VAMIANINE.

New Scientific Preparation

for the Treatment of

Syphilis, Chronic Skin Affections, Psoriasis, Acne, Eczema, Erythema, &c., &c.

Dose: 4 Pills daily, or more if necessary.

PRICE 11/- per bottle.

FANDORINE.

Internal Treatment for Women's Diseases.

Metrorrhagia, Dysmenorrhœa, Pregnancy, Lactation, Irregularities, Pains, Abnormalities, &c.

Acute Conditions: 15 to 20 tablets per day at regular interval as required. *Chronic Conditions:* 8 tablets per day between meals.

PRICE 5/- and 11/- per bottle.

FILUDINE.

Employed in all Liver Disorders.

Malaria, Diabetes, Cirrhosis, Sluggish Liver, Tuberculosis, &c.

Acute Conditions: 2 tablets three or four times daily before meals.
Chronic Conditions: 2 tablets twice or thrice daily before meals.

PRICE 11/- per bottle.

SINUBÉRASE. Complete Treatment for Intestinal Disorders.

Enteritis, Dysentery, Diarrhœa, Cholera, Typhoid, Infectious Diseases, Dyspepsia, Constipation, &c.

Acute Conditions: 12 tablets daily at the commencement of meals. *Chronic Conditions:* 4 to 6 tablets daily.

PRICE 5/- per bottle.

All the above Remedies are prepared exclusively at CHATELAIN'S Laboratories, 2 & 2 bis, rue de Valenciennes, Paris

Can be obtained from all Chemists and Stores, or direct from the Sole British and Colonial Agents—

Milk and Child Welfare

WAR conditions are making the provision of milk in adequate quantities and of requisite quality a pressing problem.

The Official Journal of the Ministry of Food, the *National Food Journal*, in its issue for October 10th, 1917, says:

> "Every effort is being made with the Departments concerned to maintain the supply of milk, but it may be impossible during the coming winter to prevent some shortage in various districts."

Special arrangements have been made by the Proprietors of the Standardised Dried Milk, GLAXO, to render available a supply of this milk for the requirements of infants and young children.

GLAXO is a dried form of whole milk, prepared under strictly supervised hygienic conditions, and provides a perfect food for babies.

The nature and use of Dried Milk is fully dealt with in Dr. J. E. Lane-Claypon's authoritative monograph, "Milk and its Hygienic Relations," published under the direction of the Medical Research Committee (National Health Insurance).

The following quotations from this representative work should dispel ignorance and prejudice regarding the use of GLAXO, and lead Medical Officers of Health, advisers of Child Welfare Centres, and general medical practitioners and all others responsible for the care of young children and the instruction of expectant and nursing mothers to make use of GLAXO.

> "The use of dried milk as a food for infants is a development of the last few years. It seems likely, however, that it is a development which will continue."
>
> "In this country dried milk is extensively used by certain municipalities and also in connection with the work for infant and child welfare which is carried out by a number of voluntary agencies."
>
> "The value of dried milk as a food is of considerable importance, both clinically and economically."
>
> "Much of the danger of contamination in the home is avoided by the use of dried milk, and there is no temptation to give the infant stale milk from motives of either economy or laziness. The milk-supply is at hand, and it can be used as required; economically it avoids waste in the homes, and if carried out on a large scale should help to reduce waste in the general supply."

GLAXO is Pure, germ-free milk of highest nutritive value, inexpensive, readily portable, easily prepared, and without any disadvantages.

GLAXO has been in use for a number of years in centres under the direction of the Health Departments of Birmingham, Sheffield, Lincoln, Rotherham, Luton, and many other towns.

Samples and full particulars will be sent to any Medical Practitioner in Great Britain and Ireland, and in Britain Overseas on application to

Glaxo

(Medical Dept.), 155, Great Portland Street, LONDON, W. 1.

Further Information, also references to Clinical Reports, will be sent on request.

PARKE, DAVIS & Co.

50-54 BEAK STREET, REGENT STREET, LONDON, W.

578

Pneumonia—
Prognosis—

Osler regards a slight or complete absence of leucocytosis as a very unfavourable sign in pneumonia.

Heart weakness due to the specific action of the poison, to the prolonged fever, or to the over-extension of the right chambers is the important prognostic feature of the disease.

Antiphlogistine

increases leucocytosis; it relieves the heart by increasing the capillary circulation, it hastens the elimination of toxins, reduces the fever, and relieves the dyspnœa and cyanosis. The use of Antiphlogistine in pneumonia is a most rational procedure; it is logical, it is reasonable, and it is scientific.

THE DENVER CHEMICAL MFG. CO., BOW, LONDON, E. 3.

"Cystazol"

Regd. Trade Mark.

This preparation is Hexamethylenetetramine-sodio-benzoate and is of great value in *Cystitis, Bacilluria and Bacterial Infections of the Urinary Tract* generally.

"Cystazol" raises the acidity of the urine and thus enhances the activity of the hexamethylenetetramine by favouring liberation of formaldehyde; on this account it is superior to all other formaldehyde compounds.

Dose: One to three tablets, dissolved in water, twice or three times daily.
Sold in bottles of 20, 1/6; 40, 2/6; 80, 4/6.

A Doctor of Medicine writes: "*I am greatly obliged to you for sending me a sample of 'Cystazol,' which I have found to be the best urinary antiseptic I have yet tried; I have been infected with Bacillus Coli for about a year and nothing has removed the offensive odour of the urine so effectually.*"

The "Allenburys" (Trade Mark) Cod-Liver Oil and its Preparations.

"It is as nearly tasteless as Cod-Liver Oil can be."—LANCET.

The "Allenburys" Cod-Liver Oil is obtained from the finest selected livers of fresh cod, and prepared at Allen & Hanburys' own factories at Lofoten and Söndmör, in Norway. It is the result of manufacturing experience of nearly half a century, and represents the highest technical skill. The process of manufacture ensures the elimination of all unpleasant and harmful products. The "Allenburys" Cod-Liver Oil is therefore perfectly pure, and by its merit alone has obtained a unique position in the estimation of the profession. It is retained and assimilated when other Cod-Liver Oils derange the digestive system, and its full nutritive power is thereby assured.

"Bynol" (Trade Mark)

"A perfect combination of Malt Extract and Cod-Liver Oil."—B.M.J.

"Bynol," the "Allenburys" Malt and Oil, presents the pure "Allenburys" Cod-Liver Oil in intimate association with the finest Malt Extract. It contains a very high percentage of Cod-Liver Oil and is a valuable nutrient and digestive. Palatable and acceptable to the most fastidious, it is readily assimilated even when the digestive organs are impaired.

"Bynin" Emulsion (Trade Mark)

"This preparation is doubtless a valuable one, and one which we are glad to bring before the notice of the profession."—LANCET.

"Bynin" Emulsion is a unique combination of the "Allenburys" Cod-Liver Oil with Bynin" pure active liquid malt, together with the hypophosphites of lime and soda. Palatable and easily digested, it is a valuable restorative of high nutritive power. It invigorates the nervous system and nourishes the enfeebled tissues.

'Bynin' Amara

TRADE MARK

FORMULA:

Quinine Phosphate	1½ grains.
Iron Phosphate	2 „
Nux Vomica Alkaloids (equal to Strychnine)	1/16 grain.
"Bynin," Liquid Malt	1 ounce.

"A distinct advance on Easton's Syrup"

THE LANCET.

"Bynin" Amara

is an analogue of Easton's Syrup, over which it has, however, marked advantages. In this product, "Bynin," a pure, nutritious, and highly active Liquid Malt, supersedes the inert basis of the official preparation.

"Bynin" Amara

is vastly superior to Easton's Syrup; the dose can be regulated with exactness; the digestive organs are reinforced and the system is invigorated by its powerful tonic action. It not only assists the digestion of food, but conserves and ensures complete assimilation.

(Trade Mark)

Styptic in Uterine Hæmorrhage

'LODAL' *(6 : 7 - Dimethoxy - 2 - methyl - 3 : 4 - dihydroisoquinolinium Chloride)* causes tonic contraction of the uterus, raises the blood-pressure and slows the heart-beat. One of the most satisfactory agents in the treatment of Uterine Hæmorrhage—*e.g.* Menorrhagia, Dysmenorrhœa not due to fibroids, and at the Menopause.

DIRECTION.—One 'TABLOID' product, taken with a little water, thrice daily.

Issued as 'TABLOID' Brand 'LODAL,' gr. 1, supplied in bottles of 25 at 1/8 and 100 at 5/0 per bottle

Little remained of the ancient kingdom of Burma after the Mongol invasion of the thirteenth century. But two centuries later a young King of impetuous temper and great ability ascended the throne determined to reconquer and unite under his sway the states which had fallen away from the monarchy. During many years he went from state to state subduing the chiefs and receiving their submission—until at last he was solemnly consecrated with the title of King of Kings. Scenes similar to the one here reproduced from a rough unfinished painting, no doubt attended this King's victorious progress. The dress worn by the victor is the ancient Burmese royal costume. Date, 1500-1570.

"MALTINE"

"Maltine" presents the proteids, carbohydrates, and organic phosphates of malt in an agreeable, convenient, and readily assimilable form. It is standardised in diastase, concentrated, and semi-liquid, and perfectly soluble.

Special Indication:—

In Infant Feeding, to humanise cow's milk and prevent constipation.

Full particulars, together with complete Feeding Tables, giving the proportions of milk and water for different ages and periods of feeding, as also samples of "MALTINE," may be obtained free of charge by Medical Men on application to the Company.

"MALTINE" WITH IRON.

Each Fluid Ounce contains—IRON PYROPHOSPHATE ... 8 grains.

This is a particularly bland and assimilable preparation of Iron, in which the astringency of the ferruginous salt is counteracted by the slightly laxative action of the "MALTINE" base.

"MALTINE" WITH COD LIVER OIL

is a complete, physiologically proportioned food, containing all the elements of nutrition in easily assimilated form, possesses valuable diastasic power, and is distinguished by its Palatability. *The British Medical Journal* states: "Apart from its own dietetic value, 'Maltine,' when combined with Cod Liver Oil, certainly enables the latter to be taken by persons who can neither swallow nor assimilate it in any other form."

The word "MALTINE" is our Trade Mark.

In prescribing kindly specify "MALTINE COMPANY."

BURROUGHS WELLCOME & CO., LONDON

A Burmese General going out to war accompanied by his body-guard. The Burmese military leaders were often very inefficient, a minister of state—perhaps some petty trader or village official—being on occasion called upon to act as General. The warriors are here depicted armed with the weapons used by their forefathers from time immemorial—the spear, the bow, and the native dha, a clumsy two-handed sword. In earlier times the General would more probably be mounted upon an elephant. His army would be more numerous than efficient, or well-equipped. A traveller to Burma in 1588 expresses his astonishment—"that in so barbarous a people there should bee such goodly orders as they have in their armies which be distinckt in squares of Eliphantes, of Horsemen, of Harquebushers and Pikemen, that truly the numbers of them are infinite, but their armour and weapons are verie naught and weak as well the one as the other, they have verie bad Pikes, their Swordes are worse made like long knives without pointes."

AN INDIAN FOOTSOLDIER, from an ancient native sculpture, armed as described by a third century B.C. Greek historian and ambassador to India: "All wear swords of vast breadth, though scarce exceeding three cubits in length. These when they engage in close fight (which they do with reluctance) they grasp with both their hands that their blow may be the stronger." The warrior's sword-belt appears to be passed through a ring attached to the scabbard over which it crosses on its way downwards to be fastened to a ring at the tip; its ends are left free like those of a scarf. The head is bare except for a band or ribbon which floats in the wind. The dress consists of a long-sleeved tunic tied in two places with cords, beneath which is the Indian dhoti or sheet of cotton cloth, with ends reaching to the ground in stiff and formal folds. High boots are worn, tied at the top with cords ending in tassels. In his right hand the warrior holds a flower. Soldiers of this class belonged to the standing army, and we are told that "they are ready whenever they are wanted to march on an expedition for they bring nothing of their own with them except their bodies." They were maintained and equipped by the King. Date: 200-150 B.C.

Obtainable of all Chemists

COPYRIGHT

Prescribed by the Medical Profession for 35 years.

The BRITISH MEDICAL JOURNAL says:
"Benger's Food has, by its excellence, established a reputation of its own."

It speaks volumes for Benger's Food that after 30 years, it is a food increasingly prescribed both in hospital and private practice.

☛ ***The following Opinions of Medical Men are of great professional interest.***

For Infants and Invalids.

"Ever since you introduced your Food, I have been in the habit of prescribing it for Infants and Invalids, and in my opinion, it surpasses and absolutely supersedes all other foods." M.B., B.S. Lond., F.R.C.S. Eng.

For Diseases of Children.

"I am a Specialist in Diseases in Children and am using Benger's Food extensively in my practice." M.D., M.R.C.S., F.R.C.S.

For Nursing Mothers.

"Invaluable for nursing mothers, especially for taking during the night when an easily assimilated food is required." M.D., L.R.C.P., L.R.C.S. Ed., L.F.P.S. Glas.

Old Age.

"My oldest patient, a gentleman of 95, refers to your Food as 'dear old Benger.' He has taken it for years; it always suits him, and he never tires of it. He has just recovered from a severe attack of pneumonia, and to show the stuff he is made of, he reads without glasses, still goes for walks, has been married three times, and has 50 grandchildren. I cannot refrain from sending you this unsolicited testimonial." M.D., C.M., M.R.C.S., &c.

Dyspepsia.

"I cannot give your Food a better testimonial than to say that I am a dyspeptic myself. I find it extremely useful and always palatable." F.R.C.S.

For Diarrhœa.

"I have found it specially beneficial in checking incipient diarrhœa as well as for feeding up babies and keeping them in condition." F.R.C.S.

BENGER'S Food *for* INFANTS, INVALIDS, AND THE AGED,
is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

The Fitz Patrick Lectures
ON
MEDICINE, MAGIC, AND RELIGION.

Delivered before the Royal College of Physicians of London,

BY W. H. R. RIVERS, M.D. LOND., F.R.C.P. LOND., F.R.S.,
FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE.

LECTURE II.[1]

MR. PRESIDENT AND FELLOWS,—In my last lecture I gave some account of the present condition of the science of ethnology in its bearing on the problems raised by the complex relations between medicine, magic, and religion. It was seen that there is a great similarity throughout the world, not only in those practices which bring medicine into intimate relations with magic and religion, but also in the domestic or strictly medical remedies so often found side by side with those used by the magician and the priest. The problem now in special need of solution is whether these similar practices have arisen independently in different parts of the earth or have developed in some one locality whence they have been carried to their present areas of distribution by the wanderings of people.

In the last lecture I illustrated certain difficulties which meet us when we attempt the explanation of these similarities on the hypothesis of independent origin. The coexistence of two more or less opposed beliefs concerning the causation of disease in America and the failure to derive the domestic remedies of a lowly Papuan people from their theory of disease are difficult to explain on this hypothesis, while they are easy to understand if the movements of mankind over the earth's surface in early times were more extensive than has hitherto been supposed.

It is one thing, however, to state a case for transmission. It is another thing to demonstrate its importance in the history of human culture. The case for this mode of explaining the similarities of human culture will only be complete when we are able to point to certain regions of the earth as the places of origin of the similar practices, and when we have discovered by whom the practices were carried over the earth and the course taken by these travellers. I propose to begin to-day with a brief consideration of the methods by which the science of ethnology is now seeking the solution of such problems as those suggested by the facts laid before you in the last lecture.

METHODS OF SOLVING THE PROBLEMS.

In considering the methods by which we may hope to attain a knowledge of the manifold changes which have taken place in the relations between medicine, magic, and religion during the history of mankind, the first point to be noted is that we cannot expect to succeed if we limit our attention entirely to the special subject we are hoping to elucidate. The social life of man is so complex, the various elements of which it is built up form so closely interwoven a structure, especially in the lowly examples of culture with which we are now dealing, that we cannot expect to understand a part except in its relation to the whole.

The Importance attached to Numbers.

I may illustrate this subject by considering for a moment a feature of medical practice in which numbers are concerned. It is the custom of certain peoples that a therapeutic measure shall be repeated a definite number of times—three, four, five, or seven, as the case may be. A striking example from Eddystone Island in the Solomons was given in my second lecture last year. In this island a treatment usually lasts for four days, sometimes for four days in each of four successive months.

This importance of the number four in medical practice is far from unique. The ancient Egyptians also had a four-day cure, and among the Cherokee of North America the normal length of a course of treatment is four days.[2]

Whether this striking agreement between ancient Egypt, the Solomon Islands, and North America is the result of the spread of culture, or whether the period of four days has been independently chosen in the three widely separated localities, is not a problem which can be settled by the study of medicine alone. Both in Eddystone Island and North America the fourfold nature of the medical rites forms only part of a system which makes the number four of the greatest importance throughout the whole range of ceremonial, whether medical, magical or religious. In both places the four-day cure is only one manifestation of a belief which ascribes special virtue to the number four.

A wider survey shows that, though we do not know of a four-day cure in Indonesia, the number is of great importance not only in religious ceremonial but also in connexion with disease. Thus, when a patient is isolated with an *adu* in front of him in the island of Nias the isolation lasts for four days. Again, in the proceedings of initiation by which a youth is fitted for the duties of a priest, his instruction in the proper use of the gong and in the appropriate formulas lasts for four days. In a different department of custom, food is put aside for the use of the ghost for four days after death, and for these four days the people do not go into the rice-fields. Again, in countries so widely separated as Greece and Japan we find a four-fold classification prominent. For Greece, I need only refer to the four elements, the four humours, &c. The question whether the existence of a four-day cure in Egypt, Eddystone Island, and North America is due to transmission or to independent origin is only part of the much larger question whether Egypt, Greece, Indonesia, Japan, the Solomon Islands, and North America possess geographical, climatic, or other features in common which have led their inhabitants to attach particular importance to the number four, or whether this number acquired in some one part of the world a religious importance with which it passed elsewhere as a constituent element of a migrant culture.

The Criterion of Common Distribution.

This need for a broad and comprehensive study becomes especially apparent in the chief method by which the ethnologist is now striving to build up schemes of the history of human institutions. For this purpose one of his chief instruments is the criterion of common distribution. If we map out the distribution over the earth of two customs between which no natural relationship can be discovered and find that the areas of distribution correspond, and if this correspondence of distribution cannot be traced to any uniform climatic or other geographical conditions, we conclude that the association between the two customs came into existence in some part of the earth and was spread thence by the movements of people, either in the course of definite migrations or for the purpose of trade.

Thus no natural connexion can be found between the worship of the sun and the practice of building megalithic monuments. When, therefore, we find these two customs associated together in some parts of the world while both are absent in others, the chances against their independent origin become very much greater than if no such agreement of distribution existed. When instead of two such associated customs we find many, the chances against their independent origin become very great.

Some Difficulties Met With.

We are at present only on the threshold of the quest by which we may hope to break up the complex web of human culture into its component strands, by which we may assign each element of culture to a definite movement of mankind. Our immediate task is to show the principles to be employed in this quest and the methods by which these principles may be applied. I propose to devote the chief part of this second lecture to certain difficulties which meet us when we endeavour to use the criterion of common distribution as our test for transmission.

If a culture has been transported over the earth from a locality in which it has developed, we must expect to find gaps in the chain of evidence. We must expect that one element of culture will fail to implant itself here and another there; that other elements will be modified in their new home, sometimes, perhaps, to such an extent as to make it difficult to recognise the relation of the final product to the custom in which it had its source. I will begin by formulating a principle which may guide us in our inquiry into such

[1] Lecture I was published in THE LANCET of Dec. 22nd, 1917, p. 919.
[2] J. Mooney: Jour. Amer. Folk-Lore, 1890, iii., 48.

cases of disappearance and modification. I shall then inquire whether it is possible to see the working of this principle when we study the nature and distribution of a small group of therapeutic and hygienic customs.

I have already suggested that a medical practice in a new home may lose its therapeutic character and become part of an indigenous magical or religious cult. On the other hand, an introduced magical or religious practice may receive a therapeutic application which it did not possess in its original home.

FORMULATION OF GUIDING PRINCIPLE.

The kind of process which ensues when a culture is transplanted into a new home may be formulated as follows. Transplanted elements of culture tend to take root in a new home in so far as they are in harmony with the physical and cultural nature of their new environment, and if they succeed in taking root tend to become modified in the direction of the indigenous culture by which they are assimilated. This proposition has two parts—one dealing with the success or failure of new elements of culture to survive in a new home; the other, with the tendency to modification which shows itself in greater or less degree in cases of success.

Factors Affecting Success or Failure of Transplanted Elements of Culture.

Physical conditions are often such as to prevent the introduction of customs which would otherwise form part of a culture-complex. Thus, the absence of suitable earth may lead to a disappearance of pottery, or the difficulty of obtaining stone may lead to the degeneration of megalithic monuments, so that they resemble those of other parts of the world in form only and not in size.

Less obvious but quite as important are characters of the social environment into which a new element of culture is conveyed. This environment may be so adverse to the newly-introduced practice that if this succeeds in implanting itself at all it soon withers and disappears under the opposition of indigenous trends of thought and action. Thus, it is probably the very different nature of the social environment of Melanesia and Polynesia which has led to a remarkable difference between these two regions in respect to their use of strictly medical practices. Medical and surgical remedies comparable with those of civilised peoples are of more frequent occurrence in Melanesia than in Polynesia. Even when strictly medical or surgical practices are found in Polynesia there is often evidence that they have only recently been introduced. This difference between the two ethnographic provinces presents us with a striking problem which seems at first sight difficult to explain either on the hypothesis of transmission or on that of independent origin. The Polynesians are undoubtedly a more intelligent people than the Melanesians, and if we take our own civilisation as the standard, Polynesian culture has reached a considerably higher level of development than that of Melanesia. If we believe that many medical and surgical remedies have been discovered independently in this part of the world, it is difficult to understand why the more intelligent and cultivated people should have fallen behind in these discoveries.

If, on the other hand, we look at the matter from the point of view furnished by the hypothesis of transmission we meet a problem of great interest. If this hypothesis is to work we shall have to find some reason why medical and surgical practices have been adopted by the lowly Melanesian in fuller measure than by the cultured Polynesian. I suggest that the reason becomes apparent if we apply the principle which I have just enunciated.

We have seen that the special characteristic of the Polynesian is the highly religious nature of his life. Disease is ascribed wholly to the action of gods and other spiritual beings, and its cure is mainly, in some cases entirely, sought by means of appeal to these higher powers. In Melanesia, on the other hand, disease is ascribed either to direct human agency or to spiritual agency which is more or less under human guidance or control. The measures employed to remedy the action of spiritual beings involve the intervention of persons whose knowledge and power are believed to be essential to success.

Let us now try to imagine the nature of the process which would follow the introduction of a medical or surgical practice among each people. There can be little question which would give it the heartier reception, which culture would be endowed with beliefs and sentiments to form the more appropriate soil for the growth of the new custom.

However closely a system of medicine be founded upon the belief in the working of a natural law, there can be no question that in fact, and still more in the minds of both practitioner and patient, success depends upon individual skill and on the human factor. If this be so among ourselves, how much more must it be true of medical and surgical remedies introduced by strangers among a people who know nothing of natural law as we understand it! Such people will inevitably ascribe any success which follows the application of the remedy to the power of the man who has brought it among them and by whom it is applied. The human factor will bulk so largely in their estimate of the value of the new remedy that its use will at once fall into line with those indigenous practices which involve the idea of human agency. To a people, on the other hand, imbued with the belief in the agency of higher powers, such remedies will not appeal. They may even be regarded as sacrilegious attempts to struggle against the will of the gods.

If, when certain medical remedies were introduced into Oceania, the differences between Melanesian and Polynesian were what they are to-day, or even if they were of the same general order, we are furnished with an explanation of the greater prevalence of strictly medical practices among the more lowly people. This example suggests how the presence or absence of an introduced medical practice may be determined by the nature of the indigenous culture into which it is received, by the degree in which it is adapted to the beliefs and sentiments natural to the people.

An example of a different kind is given in the distribution of blood-letting in the East. This practice, in the form of venesection, cupping, and leeching, is well established in India, but is almost completely absent in China, although several of the medical arts of this country are known to have come from India. Those who have recorded the absence or rarity of blood-letting in China note that it is due to the dislike of the spilling of blood which is characteristic of its people, a dislike which is chiefly responsible for the low state of Chinese surgery. That the practice of blood-letting is not indigenous in China is rendered highly probable by the existence of the dry method of cupping. If we believe that this practice has been developed independently in China, we shall be driven into the position that a people who so objected to the sight of blood that the almost universal practice of blood-letting is hardly known among them were nevertheless led to discover a highly specialised therapeutic measure which elsewhere is intimately associated with blood-letting.

Still another indication that the knowledge of blood-letting reached China is shown by the fact that leeches are used for a medical purpose. They are sometimes applied to the cervix uteri in order to induce abortion.

The absence or rarity of blood-letting combined with the presence of dry cupping and the medicinal use of leeches receives a natural explanation if the various forms of blood-letting known in India were transported to China, but met with a poor reception owing to their being in conflict with the beliefs and sentiments of the Chinese in connexion with blood, while the practice of dry cupping which does not involve the spilling of blood became an important part of their therapeutic practice.

Modification of Practices after Introduction.

I can now turn to the second branch of my subject, the modification of introduced practices due to the influence of the environment, physical and social, to which they are exposed. I may begin by considering a few examples of this process of modification taken from other departments of social life.

The modification of introduced practices occurs through the whole range of human culture. Whenever an element of culture, whether it be a word, a grammatical form, a religious practice, a social custom, or a material object passes from one part of the world to another, it tends to become changed in the process, it does not remain in its new home what it was in its old.

In the domain of language the process is so obvious that comment is hardly needed, especially to us whose speech is full of words taken from languages widely different from it-

original Anglo-Saxon basis. I may refer, however, for a moment to the words with which the English language is now being enriched as a consequence of the war. The new French and German words which are finding their way into our speech not only differ from the original in grammatical form, and still more in pronunciation, but they are acquiring special meanings, and in some cases have already assumed a form which would make it difficult for the most expert philologists to trace their origin. The derivation of the "napoo" of the British Tommy from "il n'y a plus" is a good example.

Another striking example of modification occurs in the case of decorative art. A mode of artistic expression introduced into a new home never remains the same. The art of a country resembles every other product of human society in becoming conventionalised and subject to definite laws or canons. No new form of art can escape the influence of these conventions. Thus, an introduced human motive may be changed as the result of its assimilation by a conventionalised geometrical art, so that no one would recognise the human form in the final product if it were not for intermediate forms which give the clue to its origin and development.[3]

The laws governing the modification of introduced elements of culture which I have illustrated by examples taken from language and art apply also to the practices and beliefs which make up the art of medicine. If medical and surgical practices have been transmitted from one part of the world to another we must not expect exact resemblances. Not only must we look for modifications, developments, and complications, but we must also be prepared for changes so great that without intermediate stages in the process of transformation it would be impossible to recognise a practice, perhaps no longer therapeutic at all, into which an introduced medical practice has been transformed.

EXAMPLES SUGGESTED AS MODIFICATIONS OF TRANSMITTED PRACTICES.

I shall now consider some examples in which practices, the transportation of which from one part of the earth to another I shall assume, seem to have suffered change. As I have already said, the scientific demonstration of such change can only be a gradual process resting upon a far wider study than is possible on such an occasion as this. My object to-day is rather to suggest certain medical and surgical processes as fit subjects for this line of study.

Blood-letting.

I will begin with a possibility suggested by the Chinese attitude towards blood-letting which I dealt with just now. We saw that though the letting of blood is rarely practised in China, the closely allied practice of dry-cupping takes a prominent place in the medical practice of its people. The possibility is suggested that this practice arose in China as the result of the modification of wet-cupping, as a result of the objection of the Chinese to the shedding of blood. Whether this be so or whether dry-cupping is the only survivor of a group of introduced practices is a question which can only be answered on the basis of a wider survey than is possible here.[4]

Another case in which the practice of blood-letting may have suffered modification in aim, if not in method, is suggested by the frequency of blood-letting as a religious rite. In many parts of the world the letting of blood by means of incisions or scarifications forms part of a religious ritual, while in other cases it is a feature of the customs accompanying mourning for the dead and other social practices which probably have or have had a religious significance. The problem arises whether there is any relation between this form of blood-letting and that which has a therapeutic purpose. We know a few facts which point to a connexion between the two kinds of practice. Thus, in Polynesia the letting of blood by means of gashes or scarifications as a therapeutic practice is specially characteristic of the western islands, such as Samoa, and seems to be in vogue to a much smaller extent in the Eastern Pacific. A similar difference characterises the two regions in regard to the letting of blood for religious purposes, of which we hear far more in the Western than in the Eastern Pacific. The common distribution of the therapeutic and religious forms of blood-letting in the Pacific suggests that there is a definite connexion between the two. It is possible that we have here a case in which a medical practice introduced into the highly religious atmosphere of Polynesia has come to form part of religious ceremonial and ordinary social custom, while still continuing to be used therapeutically.

Massage.

The modification of a medical practice when introduced into a new environment would seem to be well illustrated by massage. I have elsewhere[5] drawn attention to this possibility. The natives of Eddystone Island in the Solomons employ manipulations which so closely resemble those of our own massage that, if simply observed and not made the subject of special inquiry, they would undoubtedly be regarded as the equivalent of this remedy as practised by ourselves. Inquiry showed, however, that the object of the manipulations of the Eddystone leech in one case was to act upon an imaginary octopus which was supposed to have taken up its abode in the body of a patient, while in other cases the object was to extract from the body an immaterial object or principle which was held to be the cause of fever or other form of disease.

That the manipulations of the Solomon Islands stand in a definite relation to massage is rendered highly probable by the occurrence of genuine massage among the Polynesians, a people with whose culture that of Melanesia has much in common. Thus, in Samoa[6] two forms of massage are practised, each with a special name. That called *milimili* consists of gentle rubbing with the finger-tips, while the other, *tomitomi*, takes the form of kneading movements similar to those of our own practice. Both are used to remove pain and as a restorative in cases of fatigue.

In the Tonga Islands three different operations are recognised.[7] One called *milí* consists of rubbing movements, another *fota* takes the form of compression, while in the third called *tugitugi* the body is beaten. Massage is widely used in other parts of Polynesia. Sometimes it assumes peculiar forms. Thus, in the Hawaiian Islands, heavy objects are rolled along the body; in the Tongan Islands a man who is fatigued will get three or four children to trample him all over; and a similar method is used in the Eastern Pacific.

Massage is widely employed in America, and is very prominent in the therapeutic system of China and Japan. In Japan the practice is said to go back to the time of the Emperor Jimmu (660–585 B.C.). The blind are employed as masseurs, and the movements they use include rubbing, kneading, pressing, and striking according to definite rules. Chamberlain[8] records a feature of Japanese massage which is of distinct interest in relation to the point I am now considering. He notes that formerly the Japanese always massaged the limbs downwards, and have only adopted the practice of rubbing towards the trunk from Europeans. This downward direction of movements is characteristic of Melanesia and other places, where it is intended to expel injurious agencies from the body, the object being to force or induce the spirit inhabiting the limb to quit it at the extremity.

There is no question that the massage of Japan is a practice as definitely therapeutic as among ourselves, but the centrifugal direction of its manipulations suggests a relation to the belief in the causation of disease by objects or beings which it is the object of the massage to expel.

These examples are, I think, sufficient to show that there is a connexion between the therapeutic and hygienic art of massage and the manipulations by which many peoples extract or expel from the body agencies, material or immaterial, which they believe to be the causes of disease. I must be content now to raise the problem and leave for a survey on a far wider basis the consideration whether the latter usage has arisen through modification of an introduced therapeutic practice, or whether the therapeutic use has grown out of an older practice resting upon magical or religious beliefs. I will only say here that in Oceania there is little doubt about the answer. The highly developed massage of Polynesia has almost certainly been introduced into Melanesia either by the Polynesians themselves or more probably by the immigrant people who form the upper stratum of Polynesian society. If so introduced, it has certainly been modified in accordance with the indigenous ideas of the Melanesian concerning the causation and nature of disease.

Sweat-baths.

In the case of massage I have been dealing with the relation between a practice so definitely therapeutic that it forms part of our own system of medicine and a group of practices which, while still related to disease, yet bear the stamp of magic or charlatanry rather than of genuine medicine. A problem of a different kind presents itself in the use of vapour-baths which in one form or another have a very wide distribution among the peoples of the earth.

The practice of exposing the body or some part of it to heat so as to produce sweating is found in a more or less crude form in Melanesia, New Guinea, Polynesia, Africa, and America, as well as in the eastern countries from which we have ourselves largely or altogether derived the practice.[9] Thus, in Melanesia an injured limb will be exposed to the vapour rising from damp leaves or moss placed over a fire. In the Hawaiian Islands[10] the patient is enclosed in a hut within which steam is produced, and a similar practice occurs in Africa where, for instance, the Ba-Ronga[11] enclose a sick man in a small hut made of mats, and by putting a pot with live embers by his side, cause him to sweat profusely.

The country in which the vapour-bath has reached its highest pitch of development is America, where, especially on the west coast, among the advanced Pueblo Indians of New Mexico and Arizona, and among the ancient Aztecs of Mexico, the sweat-house is a most important social institution. Among many North American peoples it was the representative of the men's club-house of Melanesia and other parts of the world, which it resembled in the feature that women were rigorously excluded from its precincts. Among the Pueblo Indians the sweat-house has been described[12] as at once the bathroom, town-hall, council chamber, club-room, and church of the people.

If there is anything in common to the sweat house of America and the vapour-baths of other parts of the world, it is evident that a process of modification must have taken place. If so, there can be little doubt that this process has been one in which a therapeutic and hygienic practice introduced into America has undergone a process of development, probably through a process of fusion with other social practices, whereby it has become one of the most important social institutions of the people.

Circumcision and Sub-incision.

A striking example of modification of an introduced practice is provided by circumcision among ourselves. At the present time this operation is performed in this country for two wholly different purposes. Among one section of the population it is a religious rite, intimately bound up with the social traditions of those who practise it, while among the general body of the people it is a hygienic practice still in process of development and gradually coming more and more into vogue on account of its practical value.

There is no doubt that the great increase in the frequency of circumcision in this country is due to Jewish influence. The observation of the beneficial hygienic effects of the operation among the Jewish section of the population has made an operation which formerly only entered into our system of surgery in cases of special need one which is performed in childhood on a large section of the population. We have here a clear example in which an introduced religious practice has had a definite effect in fostering, if not in producing, a measure of hygienic surgery.

There is reason to suppose that one of the most extraordinary mutilations known to be practised by mankind is an example of a change in the opposite direction, an introduced surgical procedure having become a religious or magico-religious rite. The aborigines of Australia practise on their youth a mutilation, formerly known as the "terrible rite" and now as sub-incision, in which the urethra is opened to a great part of its length, sometimes from the perineum to the meatus. It is generally supposed that this operation is limited to Australia, and since this continent is usually regarded as one of the strongholds of the advocates of independent origin, ethnologists have been content to regard sub-incision as a wholly independent invention of the Australian aboriginal, an extension of the idea of mutilation of the genital organs, of which circumcision is the most frequent and widespread example.

A very similar operation, however, is practised in Fiji and Tonga, where it has a purely therapeutic purpose. Although the practice was originally Fijian, our most complete description of it comes from Tonga.[13] The urethra is opened and a thread passed, so that one end hangs from the artificial opening and the other from the meatus. The thread acts as a seton, and is occasionally drawn backwards and forwards so as to produce pain and the discharge of blood. The operation is a favourite remedy for tetanus, and Mariner saw several cases in which its employment was followed by recovery. The operation is also performed in cases of injury accompanied, or believed to be accompanied, by extravasation of blood into the abdominal cavity, the motive being to get rid of the blood by way of the urethra.

The close resemblance between the Australian and the Fijian practices suggests that they are related to one another. To suppose that two peoples not very remote from one another geographically, and resembling one another to some extent physically, were led to devise this extraordinary operation in total independence of one another makes too great a demand on scientific credulity. We can be confident that the practice has been transmitted from one people to the other, or, more probably, that the Australian and Fijian practices are two different manifestations of a custom belonging to a migrant people who reached both localities. Here, as in the cases already considered, the evidence is not sufficient to show the primary purpose of the operation. It seems most likely that we have here an example of a surgical remedy which, introduced into Australia among a people greatly interested in mutilation as a feature of the ceremonial of initiation into manhood, was adopted and applied to this new purpose.

SOME POINTS RAISED IN RELATION TO DISTRIBUTION OF CUSTOMS.

If the hypothesis of transmission holds good, certain practices would seem to have been modified in the process of introduction among peoples with beliefs and customs widely different from those of the locality where the particular practices had their source. My aim has been to show that in any attempt to work out the distribution of medical practices we must not study merely the obviously diagnostic and therapeutic measures, but must also look for other manifestations, sometimes in a guise strangely different from that of the original custom.

It will not be possible to consider how far we can now construct a scheme in which the practices I have to-day considered can be assigned to definite movements of mankind over the earth's surface. In the scheme of migration put forward by Professor Elliot Smith[14] to account for the common distribution of megaliths, mummification, sun-cult, and other elements of culture, one of the customs I have considered to-day, is included. The distribution of massage has suggested to Elliot Smith that this practice was carried over the earth by a people who mummified their dead, worshipped the sun, and constructed dolmens and other rude monuments of stone. It will not be possible here to consider this aspect of the subject fully; I must be content to point to a few facts which must be taken into account in such inquiries.

The distribution of the practice of blood-letting in Polynesia suggests that it belongs to a relatively late influence. It is especially prominent, both in religious rites and therapeutic practice, in the Samoan and Tongan islands of the Western Pacific, where there is reason to suspect the relatively late influence of a people who, instead of exposing their dead on platforms, interred them in stone vaults in the extended position. In Melanesia we know of the practice of blood-letting in places where the influence of the people who interred their dead in the extended position is especially prominent. The distribution of blood-letting in Oceania suggests that it belongs to the relatively late influence of a people who interred their dead. The therapeutic practice of blood-letting is very prominent in India, and there is reason to believe that it is by the movements of a people who, while influencing India, were themselves largely influenced by its culture, that the practice of blood-letting has been spread over the earth.

The practice of massage, on the other hand, occurs throughout the Pacific, and is especially prominent in the eastern islands, such as Tahiti, where the dead are mummified on platforms or in canoes. The Polynesian distribution suggests the association of massage with a movement earlier than that which carried the practice of blood-letting.

Another point suggested by the distribution of customs which I have considered in brief to-day is that sweat-baths and massage have travelled over the earth in company; just as they are closely associated among ourselves, so do they seem to be associated among many other peoples, suggesting that their diffusion was due to one and the same influence.

There are many other points which I should have liked to raise if there had been time. I can only refer here to the highly specialised character of such processes as venesection and cupping, which make it most unlikely that they have been discovered independently by the rude peoples who now practise them. I may also mention the frequent association throughout the world of the use of the cold plunge after the sweat-bath—a custom so little natural that its practice in Polynesia greatly excited the apprehensions of the early missionaries, who were evidently ignorant that a cold plunge was a feature of the sweat-bath of their own culture.

Scantiness of Available Evidence.

I have now considered a number of practices found in different parts of the world with the object of seeing how they bear scrutiny under the two hypotheses of independent origin and transmission. I hope to have succeeded in showing that the hypothesis of independent origin furnishes a very inadequate explanation of the wide distribution of these practices, and often leads us into positions wholly at variance with the primary assumptions upon which the hypothesis rests. I have not been able to bring forward any absolutely conclusive evidence in favour of transmission, nor, when transmission seems probable, have I been able to point decisively to any one movement of mankind as its vehicle. As I have already stated, this is partly due to the fact that the demonstration of transmission must be reached by an argument in which each element of culture is studied in its relation to others, so that it only becomes possible through a far more comprehensive study than is possible on such an occasion as this. My object has been rather to suggest problems and consider the principles which we must follow in attempting their solution.

One fact which makes it impossible at present to reach any positive conclusion on these topics is the scantiness of the available evidence. There are few branches of human culture about which we know so little as in the case of medicine. Owing to the intimate relations between medicine, magic, and religion much is to be learnt about the reaction of man towards disease from a study of the many researches on magic and religion which the wide interest in these subjects has produced. If the many medical men whose work takes them among peoples of lowly culture would take as much interest in the study of the ruder phases of their art as is taken by the missionary in the study of the religions he is trying to displace, we should soon be provided with a rich mass of ore from which to extract material for the construction of a history of the earlier phases of the practice of medicine.

HISTORY AND EVOLUTION.

At the beginning of these lectures I distinguished between the historical and evolutionary treatment of the subject. It is with the historical aspect that I have so far chiefly dealt with the ways in which the course of the history of medicine has been influenced by the movements of man and of culture over the earth's surface. We have seen that this course has not been one of simple progress, such as was

[13] Mariner's Tonga, 1817, ii.
[14] The Migrations of Early Culture, Manchester, 1915.

once supposed to be characteristic of evolution. On the contrary, there has been revealed a complicated process of transformation in which it seems as if therapeutic measures of a more or less advanced kind, measures perhaps founded upon a rational pathology, have been transformed into religious or magical rites or into social practices which have passed from generation to generation through the conservatism of mankind. The history of medicine as illustrated by the ruder forms of human culture seems to show a course in which degeneration has played as great a part as progress.

It must be noted that when I speak of degeneration as shown by the transformation of medical practices into magical or religious rites, this is true only in so far as their medical character is concerned. We can only regard in this light a transformation by which a medical practice has wholly lost its therapeutic character. Few will object when we regard the transformation of a medical practice into a magical rite as an example of degeneration, but when we are dealing with transitions in the direction of religion it is necessary to bear in mind that the transformed medical practice may fulfil as high a social purpose as it fulfilled in its original character.

The frequency with which we seem to have found degeneration is largely due to the special character of this study, to its special occupation with the more backward peoples of the earth, peoples among whom we might expect to find degeneration bulking more largely than it would do in a wider survey of human society. As I have already said, we are only now emerging from a period in the study of human society during which the factor of degeneration has been almost wholly neglected or greatly underrated, even in the case of the ruder phases of human culture. In seeking to show how great a part degeneration has played and is still playing in the history of human society, we must be careful not to go to the opposite extreme and overrate its frequency and importance.

Complex Nature of the Process.

If we survey the history of the practices which make up man's behaviour towards disease, there can be no question that running through the complex web of change which this history shows there has been a constant thread of progress. The degenerations and transformations shown so frequently in the history of medicine have only served to complicate a process in which man has succeeded more and more in bringing disease under control, in reducing the frequency and severity of pain, in remedying the many disabilities resulting from disease, and in rendering life longer and more secure.

This course has been complicated by two factors which have run counter to this progress. The growth of civilisation has brought with it new forms of disease or has increased the frequency of the old, chiefly as a result of inadequate adjustments of social means to the increasing complexity of social life. Thus, hardly an occupation has been developed by civilisation which has not brought with it some new form, or has increased the liabilities to some old form, of disease. Perhaps still more important has been the increased tendency to instability of the mental life due to the greater stress and strain to which advancing civilisation exposes mankind. While man has been slowly forging weapons with which to combat disease, other lines of social progress have been producing new morbid states to combat which these and still other weapons are required.

Again, the movements of mankind over the earth's surface, which have been one of the chief instruments in the progress of medicine, as of human culture in general, have themselves been the means by which mankind has distributed disease. In some cases the seeds of disease thus distributed have been the chief factors in the degeneration of culture, and in the disappearance of peoples who were the bearers of a culture from which perhaps our own advanced civilisation might have much to learn. These ways in which advancing culture has increased the opportunities for the onslaughts of disease and has distributed its seeds, only serve, however, to complicate and obscure a progress which is very real. Those who object to the crude evolutionary hypotheses of the last century do so, not because they believe the hypotheses of evolution to be false, but because their advocates have treated as simple a process which has been exceedingly complex. The opposition which is now showing itself more and more as this century progresses is not so much to evolution as to the evolutionists.

The Influence of Cultural Mixture on Progress.

Not only have these lectures led us frequently to the process of degeneration, but this degeneration seems to have been especially the result of the contact of peoples and the blending of their cultures. Here again, however, the frequency with which we have found degeneration as the outcome of this contact and blending is due to the special limitations of the scope of these lectures. If we extend our survey we find that the history of medicine resembles that of every other branch of social life in showing us an abundance of cases in which the movements of peoples and of their cultures have promoted progress. This is nowhere better illustrated than in the history of the movements whereby the cultures of India, Mesopotamia, Egypt, and Greece were brought into contact, producing a great wave of progress which overflowed to Italy and Spain, and through these channels came to have so great an influence on the medical art of our forefathers.

This influence of cultural mixture upon the course of progress has now reached a stage in which the movement of people in the older sense is no longer necessary. The universal diffusion of the art of printing has so made the world one that an advance in medicine arising in any part of the earth rapidly becomes the property of the whole. Even in the later phases of the history of medicine, however, the course has not been wholly one of progress. The history of the practice of blood-letting which this country acquired in the schools of Italy and Spain, as a legacy from the medicine of Greece and Arabia, cannot be regarded as an example of progress. At the present time I believe that we are witnessing a similar exaggeration and uncritical application of the introduced art of massage. Nevertheless, behind all these exaggerations and misapplications of introduced practices which still occur in the practice of medicine, and behind all the transformations which have characterised the different stages of its history, there stands out the vast importance of the contact of peoples and the blending of their cultures as a main, if not the chief, source of progress. The earlier history of mankind seems to have been one in which different parts of the earth were subject to long periods of isolation, relative or complete, in which progress stagnated or turned to degeneration. Then came some movement of mankind by which elements of culture were diffused, and when transplanted into places where culture had stagnated acted as the stimuli to new processes of evolution and progress. The nature of the process which took place in each region depended on many things: on the nature of the indigenous culture and of the new elements; on the relative numbers of the migrant and indigenous peoples; on the difference in the level of their cultures; on the nature of the interaction between the two peoples, whether peaceful or warlike; and on many other factors.

The Effect on Medicine of Mixture of Cultures.

Of especial importance, so far as medicine is concerned, has been the prevailing tendency of the indigenous culture in the direction of magic or religion. When a people stand at a level of culture in which medicine has a rational basis so that its measures rest on principles deserving to be ranked as scientific, the mixture of cultures will lead to development in medicine. Introduced medical practices will not only stimulate the growth of the indigenous art, but may lead to modification of the introduced practice, modifications designed to make it a more fit instrument with which to combat disease. If, on the other hand, the indigenous culture is dominated wholly by the religious attitude, the result, unless the introducers of the new art are especially numerous or powerful, may only be to deprive this of the purpose to which it is primarily adapted, and to convert it into a practice so closely associated with religion and apparently partaking so wholly of the religious spirit that it may be difficult to recognise any relation to the art of medicine.

Similarly, if the indigenous people are wholly given over to magic an introduced medical practice may so assimilate itself with the native mode of thought that again its medical character and rational basis may be lost or greatly obscured.

Not only does the comparative study of medicine, magic, and religion serve well to illustrate the complex character of human progress, but it may also teach us much concerning the nature of the evolutionary process by which

complexity is brought about. It is generally held that one of the chief features of the process of evolution is the increase in specialisation of function. That the evolution of human society is in general characterised by such increasing specialisation of social function stands beyond all doubt. We can have no better example of it than the differentiation between the leech, sorcerer, and priest which has occurred in the history of medicine, magic, and religion. It is a question, however, whether increasing specialisation is characteristic of evolution throughout, or whether it is not rather a necessary feature, I should like to call it even a necessary evil feature, of the middle stages of evolution. I believe that there are now becoming apparent in many departments of social life (I recognise it especially in that of science) indications that specialisation can be carried too far, and that with further advance we may come again to those close interrelations between the different aspects of human culture which are characteristic of its earlier stages.

The Relations between Medicine and Religion.

I will conclude these lectures by considering briefly whether this movement contrary to, or across, the growth of specialisation is not illustrated by the relations between medicine and religion.

In my lectures of last year I considered briefly the part taken by faith and suggestion in the success of the measures by which the ruder forms of human society have endeavoured to overcome the effects of disease. It is the firm belief of savage and barbarous peoples in the efficacy of the rites carried out by leech, sorcerer, and priest which is the most frequent cause of their success. As medicine has progressed and has been differentiated from magic and religion, this play of psychical factors has not ceased. Few can now be found who will deny that the success which attended the complex prescriptions and most of the dietetic remedies of the last generation was due mainly, if not entirely, to the play of faith and suggestion. The salient feature of the medicine of to-day is that these psychical factors are no longer allowed to play their part unwittingly, but are themselves becoming the subject of study, so that the present age is seeing the growth of a rational system of psycho-therapeutics. One feature of this system which is already becoming clear is that it must take account of agencies which have till now been held to be the function of the priest rather than of the physician. If medicine is to maintain its hold on certain aspects of disease which should come properly within its sphere, it must find that it has much to learn from the priest, if, indeed, some kind of collaboration between the two is not often desirable. A striking feature of the last twenty years in this country is the frequent combination of priest and physician in one person, while in America a regular system of collaboration between the two has come into being in what is known as the Emmanuel movement.[15]

As medicine comes to extend its scope to the wider study of disorder of the mind and reaches a higher recognition of the part taken by psychical factors in the causation and treatment of disease, not only will the work of the physician be found to overlap the functions of the priest but also those of the teacher, the jurist, the moralist, the social reformer. Just as there are problems and individual cases of disease which need the collaboration of priest and physician, so are there cases in which the physician, the teacher, the moral and social reformer, can help one another far more profoundly and successfully than they have done in the past.

The study of the latest phase of the history of medicine shows us a limit to the increasing specialisation of function as a character of social evolution. The relations which seem to be coming into existence between medicine and religion resemble in some degree those which we have seen to characterise the earlier phases of its history. They differ chiefly in that the later phase recognises explicitly and is learning to understand a set of conditions which were once allowed to play their part unregarded and unstudied. In the domain of the medicine of the mind—and its scope is far wider than is usually supposed—the course of history seems to be showing us that the close inter-dependence of different departments of human culture will be just as much a character of its latest and its highest phase as it was characteristic of its earliest and its lowest.

[15] See "Religion and Medicine," by E. Worcester, S. McComb, and I. H. Coriat, London, 1908.

OBSERVATIONS WITH ANTITETANUS SERUM IN THE MONKEY.

BY C. S. SHERRINGTON, M.D. CAMB., F.R.S.,
WAYNFLETE PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF OXFORD

IN the course of inquiries regarding the treatment of tetanus, it seemed desirable to the Tetanus Committee, formed under the chairmanship of Surgeon-General Sir David Bruce, to test upon monkeys the relative efficacy of the several routes by which the antitetanus serum might be injected. With that object the following series of experiments was undertaken. The monkeys employed were of various species, for the most part *Macacus rhesus* and *Callithrix*, and also less commonly *Macacus cynocephalus*, and the Jew and ringtail. There is no evidence that these several species differ one from another in their susceptibility to the tetanus toxin. Further, it is known that the anthropoid orang and the baboon are similarly susceptible.

The plan of experiment was to inoculate in the same way each animal with a like dose of toxin, and then, after the outbreak of tetanic symptoms, to inject a like dose of antitetanus serum by one or other of the following several routes: (1) subcutaneous, (2) intramuscular, (3) intravenous, (4) lumbar intrathecal, (5) bulbar intrathecal, (6) cerebral subdural. The period elapsing between the inoculation with the toxin and the injection of the serum was arranged to be similar for separate sets of experiments in which the different routes of injection of the serum were employed.

The toxin used throughout the series was the same, a sample kindly supplied by Dr. MacConkey, of the Lister Institute. As tested upon mice it had a virulence giving 0·001 mgm. as the minimal lethal dose per grm. mouse. Control experiments with it on monkeys of the species used showed that the susceptibility of these animals to it was somewhat more than four times as great as that of the mouse. The smallest dose of toxin to which the control experiments in monkeys were carried still proved fatal, although the animal succumbed then only after a relatively lengthy period—namely, on the tenth day from inoculation. That dose was 0·25 mgm. per kilo. monkey. The control experiments with the toxin were made both at the beginning and at the end of the series of experiments undertaken, and no change in the virulence of the toxin was then found.

The dose chosen for inoculation of the monkeys on which the relative efficacy of the routes of administering the serum was to be tested was in all experiments the same—namely, 2 mgm. per kilo. monkey, that is, M.L.D. for monkey × 8. The site and manner of inoculation was also in all cases the same—namely, the outer head of the gastrocnemius muscle in the region of the "nervous equator" of the muscle.

The normal course of events after this dose in the untreated monkey is as follows:—

About 30–36 hours elapse without symptoms of any kind, and then a slight flexion of the toes of the inoculated limb appears; the flexion is not irregular and spasmodic but steady and enduring. Some 6–12 hours later the corresponding ankle develops some extension (i.e., plantar flexion of foot) similarly steady and enduring. Then follows some postural extension of the corresponding hip, often with slight postural extension of knee. During the third day after inoculation the fore-limb of the same side as the affected hind-limb usually begins to exhibit an impairment in use, the animal having difficulty in feeding itself with that hand; this is due not to any inability of the hand but to slight steady postural extensor spasm at the shoulder, and sometimes, though slighter, at elbow as well. There may be at this stage some tenseness of the muscles of back and abdomen on the side of the affected limbs. About the end of the third day slight incipient locking of the jaw is usually detectable. The mouth in feeding is opened less freely than normal, as can be detected by giving the animal food from which it is accustomed to tear off a large piece, such as an apple. With soft food the symptom may be unnoticeable at this stage. The jaw difficulty rapidly increases. Retraction of the head commonly appears. The extensor postural spasm of hind- and fore-limb is all the while becoming more marked. The jaws on the fourth day are tightly clenched or only allow a slight nibbling of food. Salivation and often difficulty in swallowing appear. At the end of the fourth day, or on the fifth, general tetanus is developed in the sense that all four limbs are in rigid postural extension, there are opisthotonos and retraction of neck, and the jaw is shut completely. Death occurs usually late in the fourth or at some time on the fifth day.

The antitetanus serum employed was obtained in part from the Lister Institute, in part from Messrs. Burroughs and Wellcome. The dose of it administered was throughout the comparative experiments the same—namely, 2000 U.S.A. units per kilo. of monkey. This quantity was injected invariably as a single dose. The time allowed to elapse between inoculation with the toxin and the injection of the serum varied between 47 hours and 78 hours, and was similar for animals taken as a comparison group on which to test the relative efficacy of the different routes of serum injection. The injection of the antitetanus serum was in every case subsequent to the outbreak of the initial symptoms of tetanus.

Subcutaneous Injection of the Serum.

The site chosen for injection of the serum subcutaneously was in all cases the flank on the side corresponding with the inoculated hind-limb, the limb in which the initial symptoms first made their appearance. The results obtained by this injection are given in the following tabular statement (Table I.):—

TABLE I.—*Subcutaneous.*

Intramuscular Injection of the A.T. Serum.

The site chosen for intramuscular injection was always the inner hamstring muscle, semimembranosus, of the limb that had been inoculated with the toxin. To make absolutely certain that the serum was actually inserted into the fleshy substance of the muscle a minute skin incision was made exposing the flesh of the muscle, and into this the serum was

injected, and it could be seen that the whole of it was received by the muscular tissue. The results following this injection are exhibited in Table II.

Intravenous Injection of A.T. Serum.

Intravenous injection of the serum was made by the femoral vein of the leg not the seat of inoculation by the toxin. By a small skin incision the vein was exposed in the upper part of the thigh and the serum injected through a hollow needle inserted into the vein. The serum could be seen through the venous wall while injected. On withdrawing the needle the prick in the vein-wall closed, and there was no escape of serum or blood. (Table III.)

Spinal Intrathecal Injection in the Lumbar Region.

For these injections the animal was anæsthetised and a limited laminectomy performed in the lower lumbar region. The serum was injected by a needle-syringe through the spinal theca, which in the monkey is transparent enough to allow the serum to be easily traced by the eye after introduction into the theca and its course within the theca followed. The quantity introduced—namely, about 3 c.c., depending on the weight of the individual animal—could be seen to run rapidly both forward and backward within the theca. Usually the quantity of subdural fluid withdrawn before introducing the serum did not amount to 1 full c.c. After the serum had been injected the needle was allowed to remain unwithdrawn for about two minutes; if withdrawn directly the injection had been completed there was a constant tendency for some of the serum to run back

and escape from the theca by the puncture-hole. The wound was then closed with a few stitches, and its healing met with no difficulty. Table IV. is a statement of the results of these injections. In five of the experiments the

spinal cord was purposely slightly pricked on its dorsal surface by the needle point; this was done on account of a suggestion that the wounding of the cord, necessitating local rupture of arachnoid and pia mater as it must, might facilitate access of the antitoxin to the internal structure of the cord. The wounding of the cord gave no obvious symptom beyond a twitching of muscles locally at the time of the wounding. The experiments done in this way are marked with an asterisk.

Bulbar Intrathecal Injections.

These injections were made by exposing under anæsthesia the atlanto-occipital membrane, withdrawing through the membrane with a needle-syringe about 2 c.c. of the subdural fluid, and then injecting through the needle the quantity of A.T. serum required, usually 2–3 c.c. The injection has to be made quite slowly, and even then considerable rise in frequency of pulse and respiration ensues during the latter part of the injection and is liable to be succeeded by failure of respiration. The membrane is transparent and the serum injected can be seen to descend in part into the spinal theca, although the needle is directed forward. The healing of the wound offered no difficulty. The results obtained are shown in the following tabular statement. (Table V.)

Injections of A.T. Serum under the Cerebral Dura Mater.

These injections were all made in the parietal region over the hemisphere of the side opposite to the inoculated limb. A small trephine hole was opened beneath the upper part of the temporal muscle and the needle of the syringe thrust through the dura mater; the needle was a curved one and was so passed as not to wound the brain, except in three cases, one accidental and two intentional, the two latter with the object of making the injection a subarachnoid one. The healing of the wound offered no difficulties. The results are shown in the following tabular statement. The experiments in which the cerebral cortex was pricked by the needle are marked with an asterisk. (Table VI.)

Duration of Prophylactic Effect.

A few experiments were made on prophylaxis. These sought to ascertain how long a prophylactic dose of A.T. serum, the same in amount proportionately as that usually employed for prophylaxis in man, protects monkeys against a subsequent dose of tetanus toxin similar to that used in the above experiments—viz., 2 mgm. per kilo. The dose of anti-tetanic serum was therefore 20 U.S.A. units per kilo., and the subsequent dose of toxin was 8 times the M.L.D. for monkey. The time elapsing between the prophylactic dose of serum and the toxin inoculation varied in the individual experiments between 3 and 15 days. In five instances, the toxin inoculation having failed to produce more than merely local tetanus, the inoculation with toxin was repeated later without any intervening re-dosage with serum. The results are shown in the following tabular statement (Table VII.):—

TABLE VII.

No. of monkey.	No. of days between prophylactic dose of A.T.S. and inoculation with T. toxin.	Result.

,,	Reinoculated with toxin on 45th day.	,, ,,
9	10	,, ,,
,,	Reinoculated with toxin on 40th day.	,, ,,
10	15	Death of general tetanus in 8 days

Two control animals inoculated similarly with the like dose of the tetanus toxin, but without any prophylactic dose of the A.T. serum, died in four and five days respectively. The experiments, so far as they go, tend to show that the prophylactic dose of serum prevented the dose of toxin producing general tetanus when inoculated up to the eleventh day after the prophylactic serum, although it did not for the latter part of the time prevent the toxin dose in question producing some local tetanus. In the observations on re-inoculation the protective effect of the development of local tetanus has to be reckoned with.

AN ANALYSIS OF RECENT TETANUS STATISTICS.

BY F. GOLLA, M.B., B.CH. OXON.,

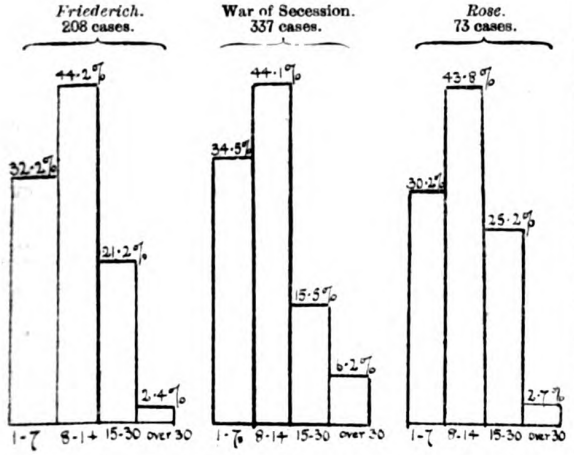
CAPTAIN, R.A.M.C. (T.F.); MEMBER OF THE WAR OFFICE COMMITTEE FOR THE STUDY OF TETANUS.

(*From the Physiological Laboratory of the University of London.*)

THE tetanus statistics under consideration deal with the period of 1916 and early part of 1917. 640 cases occurring in British hospitals in England and France have been reviewed. The cases occurring in England were collected by Sir David Bruce and those in France by Sir William Leishman. The total mortality is 50·8 per cent. and compared with the average mortality of the wars of pre-serum days the results are extremely encouraging. That in a great degree this diminution is due to prophylaxis will be shown to be beyond question, and a small part may possibly be ascribed to better methods in dealing with wounds and the consequent improvement in the general condition of the patient.

It is a matter of great difficulty in the absence of control to ascertain whether in addition to the two before-mentioned agencies the specific treatment with serum plays any part in the reduction of tetanus mortality. In the first instance it is necessary from information obtained from pre-antitoxin days to establish how far tetanus following prophylactic antitoxin injection resembles the older type of disease

Secondly, if a modification of the disease be established, the new form of tetanus must be accounted for in any comparison between recent and ancient statistics.



Tetanus in Pre-Serum Days.

The classical types of tetanus must be first considered. The symptomatology of tetanus in pre-serum days is characterised by the initial symptom of trismus. Rose, in his monumental work on tetanus, states that he has never seen a case of tetanus that did not commence with trismus, and that he could find no authenticated case where trismus as an initial symptom was excluded. This is too sweeping a statement. A small number of cases are recorded with history of local onset generally going on to secondary trismus, but they were cases of very great rarity. A certain number of cases of what was called localised tetanus are recorded in the reports on the War of Secession, but the term was used to designate not tetanus localised to the segmental wound area, but tetanus confined to trismus without tendency to spread.

The classification of forms of tetanus was then based on the rapidity and completeness with which trismus developed. Rose distinguishes "vehementes," in which the jaws cannot be separated and the complete development of symptoms takes place within 24 hours; "completi lenti," in which there is complete closure of the jaws and the symptoms take more than 24 hours to reach their maximum; "incompleti lenti," cases in which the jaws can be opened a varying degree either by the patient or the observer and the symptoms develop slowly. Other classifications have been proposed by various authors, but all of them assume the occurrence of initial trismus.

The incubation period of tetanus also followed a curve which is surprisingly consistent in three groups of statistics—

TABLE I.

those of Friederich, of the War of Secession and of Rose. (Table I.). Nor do the figures of the 1870 war differ from this type. (Table II.) About half the cases develop during the second week after the wound. About one-third develop during the first week. The cases of over 15 days' incubation form about one-fifth of the total number.

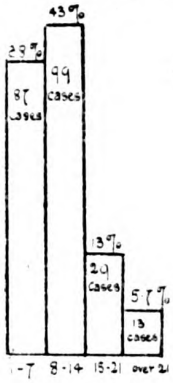
As the incubation period increases the distribution of the three types of tetanus among the cases shows a diminution of the percentage of the completi type and progressive increase of the incompleti. (Table III.)

The mortality of tetanus can only be safely deduced by reference to groups of military statistics. Collections made from medical literature are probably valueless on account of the tendency to publish successful cases. Thus Friederich in 1838 collected 252 cases with a mortality of 50·79 per cent., Curschmann in 1889 collected 912 cases with a mortality of 44·6 per cent., and Curling collected 128 cases with 54·5 per cent. mortality. On the other hand, Poland found in unselected groups of cases from civil hospitals 63 cases at Guy's with 84·2 per cent. mortality, and 48 cases at Glasgow, mortality 87·5 per cent.; whilst Rose in the Bethanien clinic had 100 cases with 86 per cent. mortality. In the War of Secession 505 cases had a mortality of 89·3 per cent. In 1870–71 the German mortality was 90 per cent. in 350 cases, or in Richter's collection of 228 observed cases 82 per cent. In the Crimea 29 cases had a mortality of 90 per cent., and Larrey, in the Napoleonic Egyptian campaign with 42 cases, recorded 82 per cent. mortality.

The values for the relation of the incidence of mortality to the incubation period in the small number of statistical collections of pre-serum days showed a considerable degree of uniformity. Table IV. gives the results from an analysis of the statistics of Richter on cases occurring in 1870–71, those of the Bethanien Hospital and those collected by Poland. These figures are all in accordance with the law that the later tetanus develops the milder the course of the

TABLE II.

Richter. Incubation of tetanus cases, 1870–71.



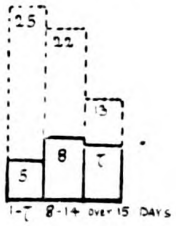


TABLE III.

Incubation of complete and incomplete tetanus. Based on *Rose's* statistics. Dotted lines = complete. Continuous lines = incomplete.

disease. Two factors combine to produce this result. Firstly, as shown in Table III., the percentage of incomplete cases increases with the length of the incubation period, but the specific gross mortality for complete cases appears from Rose's statistics to be 85 per cent., whilst that of incomplete cases is 45 per cent. Secondly, a progressive diminution of mortality goes on with the lengthening of the incubation period for each of the two categories.

From this survey of the incidence and mortality of tetanus in pre-serum days a standard of reference is established which allows the influence of prophylaxis to be distinguished from that of treatment in the new type of tetanus of the present war.

Present Investigation.

The clinical material under review consists of 316 cases occurring in home hospitals, all of which have been selected from a larger number as possessing sufficient data for the purposes of this inquiry, and 360 cases reported from British hospitals in France, of which latter 60 are without clinical notes. In addition, two sets of cases numbering 231 and 173 reported by Sir David Bruce are considered.

The clinical information does not admit of classification of the cases into the older divisions of vehementes, completi lenti, and incompleti lenti, and hence an invaluable standard of comparison is lost. The cases are for the present purpose divided into three types—those with initial trismus corresponding to the tetanus of pre-serum days, though, as will appear later, modified by prophylaxis, and two new types, those with delayed trismus and those with local tetanus. These latter two types, certainly those of local trismus, constitute a new disease and must be considered separately from cases of initial trismus if any conclusions as to the value of serum treatment by comparison with older statistics is to be arrived at.

Initial Trismus Cases: Lengthening of Incubation Period.

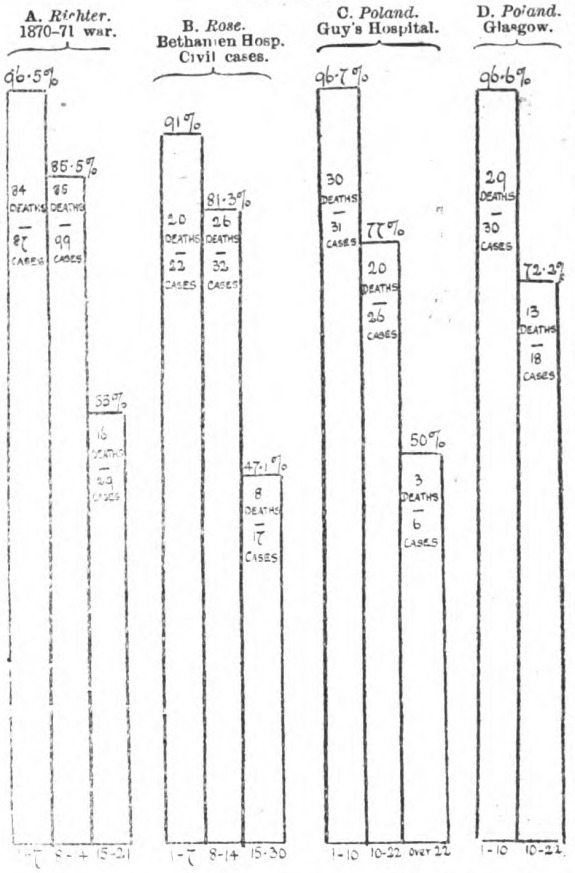

Table V. shows the incidence in relation to the incubation period of 269 cases of initial trismus occurring in England and France among the British wounded. On comparison with Table II. it will be noted that whereas in 1870 only 5·7 per cent. of the cases appeared after 21 days there are now 30·4 per cent. with an incubation period of more than three weeks. During the first three weeks a lengthening of the average incubation period is also present, though less striking.

The most probable explanation of this lengthening of the incubation period is that it is due to prophylactic treatment, and this is to some extent bore out by the three diagrams in Table VI.; they are taken from sets of cases occurring in English hospitals, and consequently exaggerate the lengthening of the incubation period, as early cases do not tend to cross the Channel. Fig. A is compiled from Sir David Bruce's statistics for 1914 when few of the cases had received prophylactic treatment and most nearly resembles the curves of pre-serum days. Fig. B is also from Sir David Bruce's statistics for 1915, when prophylaxis had been more enforced, and 77 of 173 cases were reported as protected; the lengthening of the incubation period is here more marked. Fig. C is taken from statistics of 1916, all the cases having received a prophylactic injection, and shows the most marked delay of the incubation period. Table VII. affords further confirmation that the delay of incubation is due to prophylaxis. The diagram from 47 non-protected cases occurring in the present war closely resembles the diagrams of incidence taken from pre-serum days.

Initial Trismus Cases: Mortality.

The relation between mortality and incubation would be expected to reflect the law of the inverse relation of

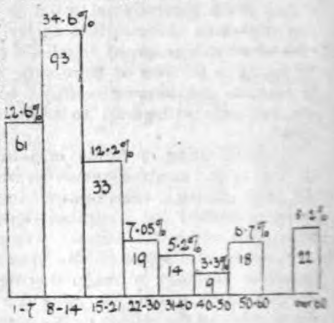

TABLE IV.

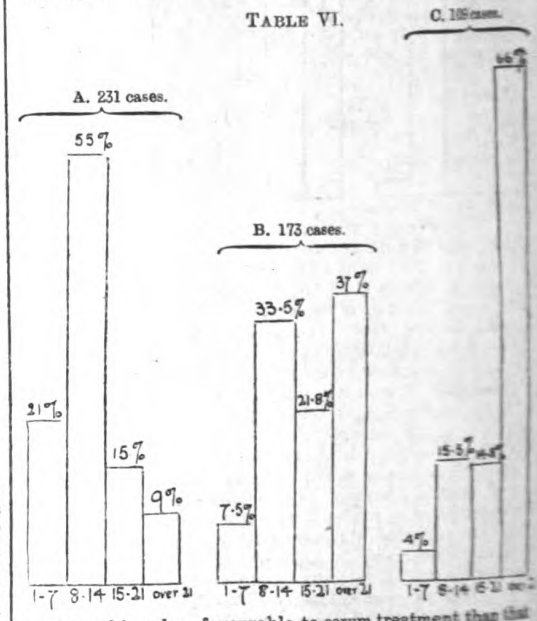
mortality to incubation, and Table VIII. fully illustrates this. It will be noted that to a very great extent the gross diminution of mortality compared with that in the 1870 campaign (Table IV.) is due to the prolonged incubation period. If, however, the first three week periods are compared it will be found that during the first two weeks the mortality in the 1916 cases is slightly below that of 1870—i.e., 75·5 per cent. and 70 per cent., as against 96·5 per cent. and 85·5 per cent.—whereas in the third week the 1916 mortality is slightly above that of 1870. This is precisely what we should expect on the hypothesis that the slight initial diminution of mortality is due to our improved methods of rendering first aid to the wounded and abstention from drastic operations. After the first two weeks when the cases of exhaustion and post-operative shock become fewer, the mortality from both statistics becomes practically the same in the third week. The same remarks hold true if Table VIII. be compared with the Bethanien and Guy's and Glasgow statistics in Table IV. On the hypothesis that the slight diminution of mortality is due to therapeutic serum treatment alone, there would appear to be no reason to account for serum treatment being less efficacious in the third week than in the two preceding weeks. It must at any rate be conceded that if the slight initial decrease of mortality is all that can be claimed for serum treatment the result is not very encouraging.

TABLE V.

Incubation of initial trismus cases in British wounded—England and France. 289 cases.



The statistics from non-protected cases, though too small to be decisive, also strongly support the view that apart from prophylaxis serum treatment has no influence on mortality. (Diagram B, Table VII.) These cases, with two exceptions, did not arise from wounds received in action; they comprise cases of slight injury which was not considered sufficiently severe to call for a prophylactic injection—cases of trench foot and cases following operation for non-traumatic lesions. They can therefore be most fairly compared with cases of tetanus arising in civil hospitals in pre-serum days. The statistics of Rose and those of Poland for Guy's Hospital show a combined mortality of 79 per cent. The mortality for the British non-protected cases is 75 per cent. The difference is therefore trivial.

Cases of Late Trismus.

The separate consideration of cases of late trismus is justified by a consideration of Diagram A, Table IX., showing the enormously increased incubation period. The curve showing the relation of mortality to incubation (Diagram B)

TABLE VI.

is, if anything, less favourable to serum treatment than that of the initial trismus group; the difference in the gross mortality between initial trismus, 62·5 per cent., and late trismus, 42·25 per cent., is obviously due to the high percentage incidence of late cases in the latter group.

Table X. shows the percentage incidence and mortality of all cases of trismus both initial and late.

TABLE VII.

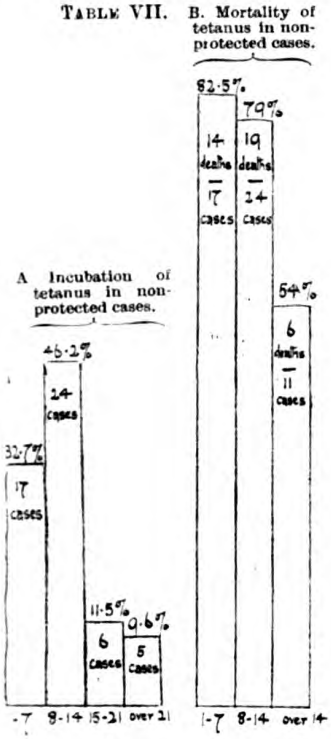


TABLE VIII.

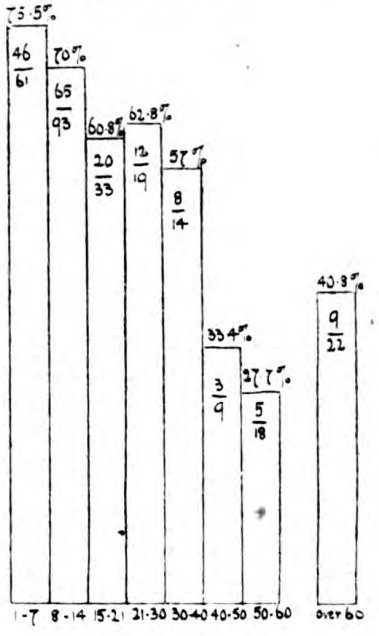
Mortality of initial trismus cases in English and French hospitals.



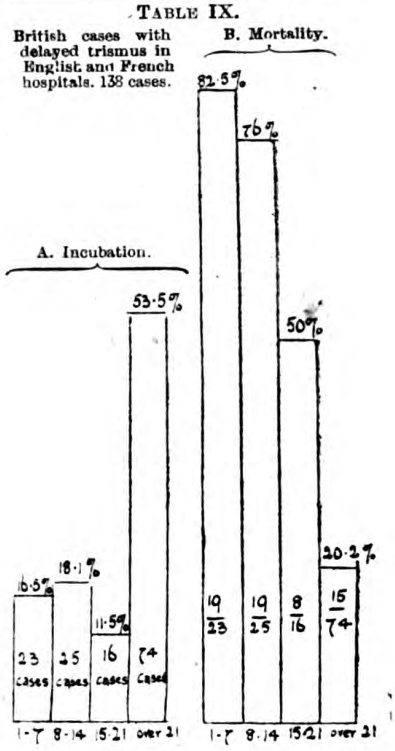


TABLE IX.

British cases with delayed trismus in English and French hospitals. 138 cases.

Local Tetanus.

Local tetanus appears to have no mortality; four cases of death when only true local tetanus has occurred have been found in the statistics, but in the absence of more definite evidence than their clinical notes afford there does not appear to be sufficient reason to ascribe death to tetanus.

Table XI. shows the relation of the occurrence of local tetanus to the incubation period (Diagram A) and Diagram B the relative percentage of local tetanus in all types of cases. The effect of the dilution of statistics of tetanus with local tetanus is shown in Table XII.

The Curative Action of Serum.

To sum up, there appears no evidence of any appreciable diminution of the mortality of tetanus to be derived from an analysis of the statistics of incidence and mortality when allowance is made for the modification of the disease due to prophylaxis.

Another infallible sign of a curative action of serum should be furnished by an examination of the time after the onset of symptoms at which treatment was begun in fatal and cured cases. In animal experiments the interval of time after toxin injection during which antitoxin can act

TABLE X.

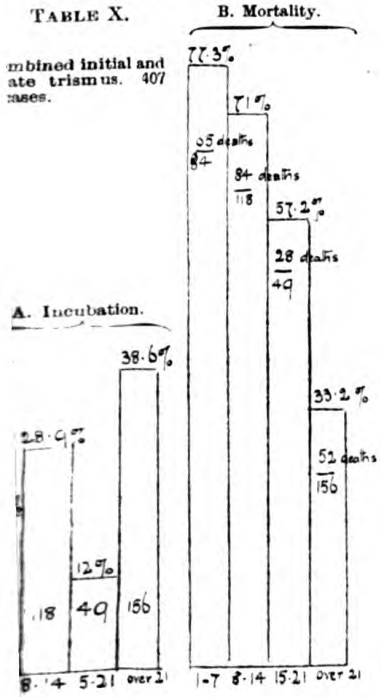

TABLE XI.

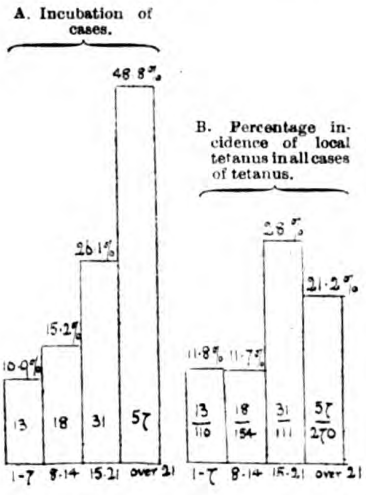
Case of local tetanus without trismus.



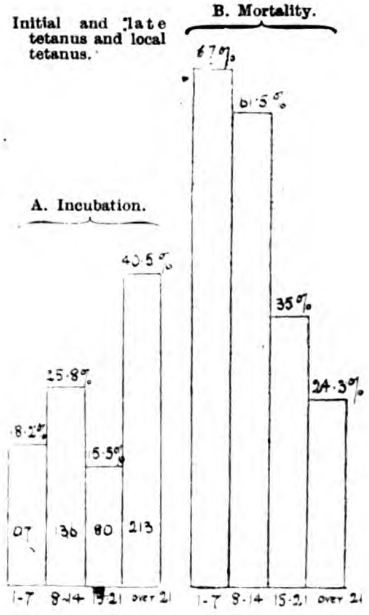


TABLE XII.

Initial and late tetanus and local tetanus.

effectively admits of very accurate definition. Sir David Bruce has pointed out that an examination of the gross statistics shows no such relation. As it might be objected that in slighter cases there is a tendency on the part of the doctor to delay treatment, 50 cases of tetanus with initial trismus have been selected. All of them, as far as the notes allow evaluation of the symptoms, were cases of similar gravity. Again, no evidence could be elicited from this rather laborious inquiry. The periods before beginning of treatment varied from 30 minutes to three days, and no relation between their duration and the result of the disease could be established.

It might be anticipated that if antitoxin had any curative influence a relation would be found between the amount of serum administered and the result of the case. The total amount of serum administered in different cases cannot be compared, as with a longer illness, and hence a better chance of survival, the amount of serum dispensed will be greater. If the average daily dose be considered, no relation between its size and cure can be established. Sir David Bruce found in 165 cases 104 were treated with a daily dose of under 5000 units with 49 per cent. mortality, and 61 received over 5000 units with 53 per cent. mortality.

To get rid of the objection that the milder cases received the smaller dose the daily serum dose was estimated in the 50 cases of initial trismus already mentioned. The analysis showed that cases recovering received on an average 5500 units daily, while the dose for fatal cases averaged 7000 units daily.

The statistics were worthless for any attempt to discover the influence of different methods of administration. In the home hospitals the majority of the cases treated by the subcutaneous and intramuscular methods were of a mild character.

In view of the wealth of English statistics there is little to be gained at present by seeking additional evidence on the effect of serum treatment among the records of other belligerents. Only papers dealing with relatively small groups of cases, chiefly from single clinics, are at present available, and none of them attempt to analyse the type of case dealt with from the standpoint of the incubation period.

Experimental Work in Regard to Treatment by Serum.

With so little encouragement from clinical evidence the support afforded by experimental pathology requires to be scrutinised critically. The possibility of neutralising toxin in an experimentally injected animal by a timely injection of antitoxin is admitted on all sides to be subject to the condition that a sufficient quantity of antitoxin has not already entered into the central nervous system. The superiority of intravenous and intrathecal methods of injection over the slowly absorbed subcutaneous and intramuscular is a necessary corollary, and has been repeatedly established experimentally. The failure of serum in man means primarily that by the time symptoms of tetanus appear a sufficiency of toxin is already in the nervous system in such cases as would end fatally whether treated or not, whereas in the milder cases sufficient toxin to cause fatal tetanus is not manufactured. There are, doubtless, many other factors to be considered; thus in the experimentally injected animal the injection mass of toxin lies loose in the tissues, whereas in man the tetanic focus is often shut off by a wall of inflammatory tissue and inaccessible to antitoxin, whilst toxin can reach the central nervous system from the focus by direct entry into contiguous nerves. To give information of direct value on the question of treatment it appears to be desirable to begin experimental work on antitoxin *de novo* on animals with septic wounds infected with tetanus culture.

The recent work done for the War Office Tetanus Committee by Symes, in that it tends to confirm the views of Meyer and Ransom that the passage of toxin up the nerve takes place by the nerve fibres rather than by the perineural lymphatics, should make the chances of successful treatment of absorbed toxin less hopeful. During the past year some experiments of Professor Sherrington showing that intrathecal administration of antitoxin is more efficient than intravenous in the monkey have revived the hope that a local immunity of parts of the nervous system not already reached by toxin may be established. The results are exceedingly interesting and furnish incontestable evidence that under the conditions of his experimental intrathecal injection of antitoxin he has effected a local immunisation of the bulbar region in which the rest of the cord does not appear to share. It is, however, by no means evident that these results can be directly interpreted as an argument for injection of antitoxin into the lumbar cisterna of man, and, as a matter of fact, clinical evidence does not show a similar superiority of the low intrathecal injection in man over the intravenous method. Thus Irons, in a series of unselected cases, found with 16 acute cases treated by the lumbar method the mortality was 81·2 per cent., and with 11 acute cases treated intravenously the mortality was 72 per cent. The chronic cases were too few in number to admit of a fair comparison.

A CASE OF SPLANCHNIC TETANUS.

BY H. BURROWS, M.B., B.S. LOND., F.R.C.S. ENG.,
CAPTAIN, R.A.M.C. (T.F.).

THE following case is worthy of record as an example of splanchnic tetanus, ending fatally, and yet unaccompanied by trismus or general convulsions.

The patient, Private H. A., was wounded on June 30th 1917, and admitted to —— General Hospital, under the care of Major H. A. Moffat, on July 3rd. There were three septic shell wounds—in the left arm, left leg, and left thigh respectively. The patient had received a prophylactic dose of 500 units of antitetanic serum on the day of his wound. On the morning after admission to —— General Hospital he was found to have symptoms of infarction of the base of the right lung, with hæmoptysis, pleural friction, and deficient air entry.

July 8th: Wounds not cleaning well. Thigh and buttock wounds dry and sloughy. 9th: Second dose of 500 units of antitetanic serum given subcutaneously. 10th: Carrel-Dakin treatment commenced. 12th: Cough and expectoration much less. Wounds looking more healthy. 18th: More pain in right lower chest. Sputum no longer blood stained, but purulent.

On July 19th (the twentieth day after receipt of the wounds) Major Moffat made the following note: "Does not seem at all well; he is nervous and jumpy; every few seconds neck and chest muscles cause a kind of shrug." Sterno-mastoids and other muscles of the neck were persistently hypertonic, but there was no trismus. An intramuscular injection of 1500 units of antitetanus serum given.

On July 20th there was persistent hypertonus of muscles of neck, including the trapezius on each side. Percussion of these muscles caused them to contract spasmodically. No trismus was present. The muscles of respiration were hypertonic, so that patient could not cough or take a deep breath; and breathing was of the automatic type—that is to say, the respiratory excursions did not vary in amplitude, and there was no expiratory pause. There were no clonic respiratory spasms. There was a slight increase in the frequency of respirations, and a considerable increase in the frequency of the heart beats. Sweating was profuse.

On July 21st patient was much worse. Any attempt to cough or to take water or nourishment caused violent respiratory spasms in which the muscles of the neck and spine took part. Probably there was some pharyngeal spasm also, but the respiratory spasm was so quick of onset and so urgent that it was sufficient to prevent patient altogether from swallowing. There was no trismus, nor was there any involvement of the limbs. The knee-jerks were not increased, there was no ankle clonus, and no tetanus reflex was obtained on tickling the soles of the feet. The patient was very restless, tossing about in bed and throwing off the bed-clothes. His face denoted fear and acute apprehension. It was doubtful whether the spasms were painful or painless. Probably they were not very painful. They caused intense distress through the fear of asphyxia that accompanied them. During the spasms the bowel and bladder acted.

On July 22nd patient became comatose and died. Temperature rose to 106·4° F. before death. It was noticed that the pupils were unequal, the right being larger than the left, but neither was pin-point. The temperature showed a diphasic afternoon rise, the range being: July 3rd–6th: T. 97·6°–100·4°, P. 94–120, R. 22–80. July 7th–8th: T. 98·8°–102° P. 112–120, R. 24–28. July 9th–12th: T. 99°–102°, P. 92–120 R. 20–28. Thereafter the temperature was not above 101° until the rise before death.

The following doses of antitetanic serum were given: subcutaneously, 500 units on June 30th and July 9th; intramuscularly, 1500 units on July 19th, 4500 units on July 20th and 21st.

Post-mortem.—There was a small localised empyema at the base of the right pleura, the adjacent lung being solid. There was an ante-mortem effusion of blood at the base of the

pons, in the cisterna magna, and spreading around the sides of the pons. Portions of the infarcted lung were sent to Captain A. W. Stott, who made the following report: "Bacilli morphologically resembling *B. tetani* grew in broth anaerobically, but failed to produce symptoms of tetanus in a mouse and a rat inoculated subcutaneously with the culture."

There are several points about this case which are of particular interest. In the first place, the symptoms closely resembled those of hydrophobia. Secondly, the total absence of trismus was a remarkable feature, for in splanchnic tetanus even occurring in the modified or local form one would expect to find trismus accompanying the respiratory spasm. The absence of involvement of the limbs also was a striking feature, for the patient tossed his limbs and even fanned himself during the respiratory spasms.

Splanchnic tetanus, as is known, follows infection through wounds of the chest or abdomen. In this case there was no immediate infection in these regions, and one must suppose that it reached the chest by means of the pulmonary infarct. And in spite of the fact that the bacteriological findings were doubtful on this point, I think one is still justified in assuming that the infarct was the place where the fatal toxin was manufactured.

The hyperpyrexia and unequal pupils appearing shortly before death are perhaps attributable to the hæmorrhage around the pons, which doubtless occurred during and as a result of the spasms.

In conclusion, I should like to thank Major Moffat for allowing me to publish the details of the case.

NOTES ON TEN CASES OF TETANUS.

BY REDCLIFFE N. SALAMAN, M.A., M.D. CANTAB.,
CAPTAIN (TEMP.), R.A.M.C.

DURING the 11 months in which I acted as tetanus inspector in the Colchester district there occurred 10 cases of tetanus. The clinical histories are given at the end of these notes, as well as that of a case (7A) which proved not to be tetanus, but was of interest from the point of view of diagnosis.

The cases are all too few to draw any deductions as to treatment, and more especially as to the vexed question of the best route for the administration of antitetanic serum. The object, however, of publishing these notes is to draw attention to certain points which have a clinical interest and value.

Summary of Cases.

Tables I. and II. classify the cases according to the method now used on the revised Tetanus Inspector's Report and give particulars as to prophylaxis and treatment. Four of the 10 cases died, of these:—

CASE 1 had the most acute tetanus and would have died therefrom probably apart from his severe loss of blood and operation.

CASE 4 was suffering from a fourth attack of tetanus of a subacute type; he died in acute spasm eight hours after an intrathecal injection. No explanation is offered, unfortunately a post-mortem examination was not made.

CASE 6.—This patient had a hæmothorax and was very severely injured. The tetanic condition was not acute, but the treatment in the early stages was inadequate. Death was due to broncho-pneumonia and heart failure, and not to tetanus.

CASE 8.—This patient had an intensely acute attack, and would have probably succumbed in any case. Treatment was inadequate in the earliest stage.

Of the cases that recovered none were acute. They reacted rapidly to treatment with antitetanic serum. It is perhaps permissible to say that the life of Case 2 was saved by treatment. As regards the remainder it is very possible that they would have recovered in any case.

Observations on Points of Interest.

Examples of all the types mentioned in Table I. occur; two cases deserve special notice, however: No. 7, in which trismus was the only symptom complained of by the patient or recognised at the time he was seen, and No. 9, in which the tetanic condition was absolutely localised to the group of muscles surrounding the wound. This case would have probably escaped notice had he not been in my own ward at a time when I was particularly on the look-out for this type of tetanus. He was seen by Colonel A. Carless, who agreed in the diagnosis.

Generally there is no difficulty in diagnosing tetanus, but in two of the cases such difficulty did occur, viz., in No. 7 and No. 7A. In the former, as already mentioned, the only symptom was slight trismus associated with loss of the swinging movements of the jaw. In No. 7A there was a greater degree of trismus but no loss of the swinging movement. I had already observed the constancy of this loss of swing in connexion with the trismus of tetanus, but I felt it my duty to give No. 7A the benefit of the doubt and advised active serum treatment. The end-result—complete recovery of opening and swing movement in No. 7, and no alleviation of the condition in No. 7A—confirmed the diagnosis and incidentally the value of this sign.

An effort was made to examine the wounds bacteriologically, but the opportunities were very limited. In Cases 1 and 2 round-end sporing anaerobic bacilli were discovered, and in Case 2 tetanus bacilli were found at the Royal Army Medical College. In Case 2 three examinations of pus from the wound were made—viz., one at the commencement of the treatment, one five weeks later, and a final one four weeks after the second. In the first there were abundant anaerobes, including round-end sporing rods. In the second and third there were no round-end sporers and the amount of other anaerobes present was much less. The suggestion that antitetanic serum may have a bactericidal

TABLE I.—*Classification of Cases.*

	No. of cases.	Mortality per cent.
A. Trismus initial symptoms—		
1. Tetanus with complete closure of jaws (teeth cannot be separated) developing within 24 hours of symptoms	2	100
2. Tetanus with complete closure of jaws, developing in more than 24 hours	—	—
3. With incomplete closure of jaws. Mouth can be partially opened	4	0
B. Trismus occurring after other symptoms have developed	2	50
C. Local tetanus without trismus	2	50

Total mortality = 40 per cent.

action would not seem improbable, and in this relation the fact that in the 6 cases which recovered the condition of the wounds improved markedly whilst the patient was under serum treatment is worthy of note.

In Case 2 four intrathecal injections were made, and at the second the cerebro-spinal fluid was found to be turbid and loaded with leucocytes. Bacteriological and histological examination showed it was sterile; a further examination at the fourth puncture gave similar results. That intrathecal injections do cause irritation of the meninges is, of course, recognised, and one is tempted to ask whether the death of Case 4 after an intrathecal injection could have been due to this cause.

The classification adopted by the Tetanus Committee meets satisfactorily the ten cases that are here dealt with. The two cases Nos. 1 and 8, in which there were no prophylactic injections, were of the most acute type and fall naturally into Type A, 1. It is not always easy to differentiate between Divisions 2 and 3 of Type A, and so far I had no case which could be placed in Type 2. A comparison of the time of incubation, Col. 2, Table II., and the classification shows that the old relationship between rapidity of incubation and severity of disease does not hold in those cases where prophylaxis is practised.

Clinical Notes on Cases.

CASE 1.—R. B., aged 31. Wounded over left clavicle on May 1st, 1916. The wound healed rapidly, but the patient was left with some paresis of arm. No notes as to foreign body. On July 8th he was transferred to an auxiliary hospital; here a swelling developed over the left clavicle, which was incised on Oct. 9th on the assumption that it was inflammatory. Violent hæmorrhage ensued, and the cavity was hastily packed and the patient sent to the local general hospital for operation, where the axillary artery and vein were tied. On Oct. 13th trismus was observed, followed by risus sardonicus, and later very frequent general spasm. The operation wound was very extensive and extremely purulent. The patient died next day. He was given 12,500 units intrathecally, 6500 units intramuscularly. His general condition after the hæmorrhage and operation was so bad that it is improbable that he would have survived apart from the tetanus.

It is unknown whether this patient had a prophylactic injection of serum in France, he had none in England. In the wound were found many anaerobes, but no terminal round sporing ones. Inasmuch as these anaerobes must have arisen from contamination during the operation of Oct. 9th, it is to be assumed that the tetanus infection took its origin at the same time and was not a recrudescence.

CASE 2.—J. C. Severely wounded right upper arm and shoulder, with much bone destruction, on July 28th, 1916. The wounds remained dirty and the condition of the patient unsatisfactory, notwithstanding continuous and careful treatment. On Nov. 10th the patient did not feel so well. He described his condition as "feeling funny and queer all over"; took his food well; had no cramp or pain. Next day he could not eat his breakfast because of stiffness of jaws. Two hours later he had two attacks, separated by a few minutes, of clonic spasm in the right leg; forehead chronically contracted and a mild degree of risus sardonicus. Treatment was begun at once and energetically pursued by all routes. Sequestra were removed on eighteenth day of treatment. The condition of the wound improved markedly whilst under antitetanic serum, and the patient not only entirely recovered of the tetanus, but three weeks after the onset of the attack was in a decidedly better state of general health than before. 101,100 units of antitetanic serum given in all.

The patient stated that he had a prophylactic injection on July 29th, 1916. He received no other.

CASE 3.—C. C., aged 25. Wounded on Oct. 15th, 1916. Clean penetrating wound of left upper arm; no bone or nerve injury. After treatment in Norfolk War Hospital patient was sent to an auxiliary hospital for convalescence and discharged on furlough to duty. He complained of rheumatism in the left arm about Dec. 13th, and felt heavy and dull and had a bad headache for some days. After a few days of treatment at home by rubbing with embrocation he walked three miles there and back to see a doctor, and was sent by him to Colchester General Hospital. He stated that the farther he walked the worse he got, so that by the time he returned home not only his arms and shoulders were stiff, but his back and legs.

On admission the left elbow was fairly flexed at 60° and the tone of the upper arm and shoulder muscles greatly increased. The jaw was fixed to within ¼ inch between the edges of the incisor teeth and lateral movement abolished. Improvement as regards the movement of jaw and elbow was rapid, but the increased tone of muscles persisted long after all other symptoms had vanished, and was not gone till the end of the fourth week, although treatment was persisted in. The patient received 109,500 units, mostly intramuscular.

The patient stated that he had one injection of antitetanic serum on Oct. 15th, 1916. He received no other prophylactic doses.

CASE 4.—B. H., aged 21. Wounded on Sept. 15th, 1916. Compound fracture of left humerus. The wound healed completely. The patient stated that he had an attack of tetanus three weeks after wounding, that he recovered in three weeks, but at once relapsed and had tetanic symptoms for two weeks. Two months later he had a third more severe relapse. The attack here described was the fourth.

The patient was admitted to the Military Hospital, Lakenham-road, Norwich, on March 9th, 1917. The left side of the body was quite stiff, but no opisthotonos, frequent spasms on the left side of the body without pain, could only open his mouth half way. He was given 4500 units of antitetanic serum int amuscularly at once. At noon on the 10th, he was anæsthetised and I withdrew about 40 c.c. of clear cerebro-spinal fluid and injected 37 c.c. of serum containing 12,000 units and 4300 units intramuscularly. At 5.30 P.M. the patient was comfortable, spoke freely, and had an excellent pulse. At 6.30 P.M. he began to breathe heavily and severe tetanic spasm with opisthotonos, risus sardonicus, and clenched jaws supervened. At 8.15 P.M. he died.

Before giving the intrathecal injection the patient presented the symptoms of a subacute case and good hopes were entertained of his recovery. The sudden exacerbation of symptoms was quite unexpected and would seem to have been the result of the intrathecal injection. There was no question of anaphylaxis.

Nothing is known of any prophylactic injections, but he stated that he was treated with frequent injections in his previous attacks.

CASE 5.—Corporal H. W., R.F.C., aged 19. Wounded on March 28th, 1917, in an aerodrome at home on the scalp, which he soiled by touching his head with his muddy hands. On the evening of the 30th the patient developed stiffness of jaw, neck and limbs; movement of arms and legs gave rise to pain; the teeth could be separated only ⅛ inch and lateral movement of jaw was restricted. He had much difficulty in swallowing. Knee-jerk dull. Plantar reflex normal. On the 31st treatment was begun with 12,000 units intramuscularly and was continued till April 7th, when the patient had received 40,500 units. He made an uninterrupted and rapid recovery.

Although the symptoms were developed on the sixth day of a wound in the head and were of an extensive, though subacute, type the patient showed enormous improvement 24 hours after the first intramuscular injection and recovered completely within eight days of the onset.

CASE 6.—H., aged 32. Wounded on April 11th, 1917. Comminuted compound fracture of right arm and extensive flesh wounds of neck and back. Stiffness of neck was noticed on April 20th. The patient was sick on the 22nd, slow tetanic spasms of shoulder muscles and pectorals followed, and the nature of the case was realised on the 24th, when treatment began. Foreign body was removed under an anæsthetic on the 26th. The symptoms increased after this, and stiffness of the jaw was noticed on the 28th. The case was not notified till May 1st. On this date the jaw was locked to within ¼ inch between the incisor edges and lateral movement abolished; mild risus sardonicus. Knee-jerk = ++. Prior to this an intravenous injection of 24,000 units and 9000 units intramuscular were given. The general spasms and condition of the jaw showed immediate improvement, which persisted until the end. Unfortunately the patient had developed broncho-pneumonia soon after admission to hospital, and he died on May 5th apparently from this cause and with accompanying heart failure.

Patient stated he had a prophylactic injection on April 11th. Details of serum treatment are given below. It is probable, seeing how readily the tetanic symptoms reacted to treatment, that had the treatment been carried out energetically from the beginning the toxic affection of the heart might have been avoided and the case might have been saved.

Day of illness.	Intramuscular.	Intravenous.	Day of illness.	Intramuscular.	Intravenous.
4	500	—	11	—	24,000
6	2,000	—	12	6,000	24,000
7	5,000	—	13	14,500	—
8	12,000	—	14	2,500	—
9	12,000	—	15	6,000	—
10	18,000	—			

CASE 7.—A. S., aged 20. Wounded on April 25th, 1917. Compound fracture of right arm, with gas gangrene, amputation at shoulder-joint. The only symptom complained of by the patient was stiffness of the jaw dating from May 13th. The nurse had noticed some slight tremors of the left hand, but apart from this trismus was the only really definite tetanic symptom. The swinging movements of the jaw were markedly limited and separation of jaws was limited to ¾ inch between the incisors. There was no increase tone of muscles in neighbourhood of the wounded shoulder. The patient was treated by the intramuscular route, receiving 60,000 units in 11 days. Recovery was complete.

This case presented some difficulty of diagnosis, and the medical officer in charge was doubtful as to its true nature, but the limitation of lateral movements of the jaw was convincing.

CASE 7A.—Second Lieutenant C., aged 32. Wounded at bombing practice in England on May 25th, 1917. Penetrating ragged wound right chest, with hæmathorax, numerous lesser wounds about the body, destruction of left eye, and a small wound of left cheek, with minute foreign body in buccal muscles. On June 5th the patient noticed stiffness of jaw, the opening between incisors was limited to 1 inch. No difficulty in swallowing and complete freedom of lateral swinging movements of jaw. Knee-jerk normal. On the 6th there was slightly increased tone of the left masseter and also to a lesser extent of left trapezius, but none in the other shoulder muscles. The wound in the cheek was so slight that no dressing was applied. On the supposition that tetanus was present 60,000 units of antitetanic serum were given in a few days, but, although the general condition of the patient improved rapidly, the inability to open the jaws continued. On July 3rd the patient was entirely recovered except for the jaw movement, which was still limited to 1 inch between the incisors, although the lateral swinging movement was perfect. Palpation of the left masseter now shows a quite definite fibrous thickening of the anterior lower segment. This case was evidently not one of tetanus.

CASE 8.—C. R. S., farmer, aged 46. On July 13th, 1917, the patient, who had been under treatment some months for neuritis with double drop foot, slipped whilst walking in his kitchen garden and sustained a slight abrasion of the thumb. The path on which he fell had recently been soiled by an overflow of rain water coming from an adjacent highly manured bed.

On July 21st the patient developed trismus, with complete closure of jaws and general tetanic symptoms. Treatment was begun on the 22nd, but was not energetic. I visited the case on the 28th and gave 16,000 units intrathecally and 16,000 intramuscularly. The condition, however, of the heart and commencing œdema of the lungs was such as to preclude success, and he died on the 29th, the tetanus symptoms having considerably reduced in severity from the 27th.

Details of serum treatment are given below.

Day of illness.	Subcutaneous.	Intramuscular.	Intrathecal.	Day of illness.	Subcutaneous.	Intramuscular.	Intrathecal.
2	1,200	—	—	6	—	8,000	—
3	3,000	—	—	7	—	8,000	—
4	—	16,000	—	8	—	16,000	16,000
5	—	16,000	—	9	—	8,000	—

CASE 9.—McD., aged 27. Wounded on July 24th, 1917. Small penetrating wound at middle of flexors left thigh. Foreign body removed. The wound was healed on admission to hospital on August 3rd, 1917. Examination of the wound that day revealed a very definite tonicity of the muscles on the flexor surface of thigh around the wound and manipulation of the group elicited a spasmodic contraction of the whole limb. The patient complained of nothing, but on questioning volunteered the statement that a week after his wound when walking on the gravel path he noticed how the rough surface made his left leg jerk. Knee-jerk = ++. Plantar reflex flexor. The Achilles tendon-jerk obtained on left only, on which also could be demonstrated a pseudo-clonus of the ankle. Jaw muscles entirely unaffected. Treatment by intramuscular route 48,000 units in 13 days. complete recovery.

The patient had received a 500 unit prophylactic injection on July 24th.

CASE 10.—O., aged 20. Wounded on June 28th, 1917. Compound comminuted fracture of left ankle. After six weeks' Carrel-Dakin treatment of the wound, during the last two of which the patient was in my own ward, he casually remarked one morning that he had a pain at the back of his neck. Investigation showed that, whilst nothing definite could be made out at that spot, there was very marked trismus with complete absence of lateral jaw movements, some difficulty in eating which the patient had observed for five days, but had not considered worth mentioning, greatly increased tonicity of the abdominal muscles, and jerky sensations in the injured leg. Knee-jerk right leg = +.

Treatment was entirely intramuscular, 48,000 units in nine days, resulting in complete recovery of all tetanic symptoms and a marked improvement of the condition of the wound whilst under the influence of the antitetanic serum.

The patient had received a 1500 unit prophylactic injection on June 28th.

Barley, Royston, Herts.

Reviews and Notices of Books.

White and Martin's Genito-Urinary Surgery and Venereal Diseases. By EDWARD MARTIN, BENJAMIN A. THOMAS, and STIRLING W. MOORHEAD. Tenth edition. Illustrated with 422 engravings and 21 coloured plates. London and Philadelphia: J. B. Lippincott Company. 1917. Pp. 929. Price 30*s.* net.—In the present edition the twenty-years-old text-book has received a thorough revision at the hands of Dr. Thomas and Dr. Moorhead, respectively professor of genito-urinary surgery to the Polyclinic Hospital and assistant surgeon to the Howard Hospital, Philadelphia. The book has been kept back for this purpose and has been long out of print. Such recent developments as the tests of renal function, the laboratory diagnosis and control of treatment of syphilis, the value of serums and vaccines, separately and combined, receive sufficient mention. The authors do not accept without independent study the opinions of others and deprecate the routine antisyphilitic treatment of symptomless patients in whom the Wassermann reaction persists. In its present form the book will be found of practical service by all who are engaged in the treatment of genito-urinary and venereal disorders.

Reagents and Reactions. By EDGARDO TOGNOLI, M.D., Professor in the University of Modena. Translated by C. A. MITCHELL, B.A. London: J. and A. Churchill. 1918. Pp. 228. Price 6*s.*—Many reactions are still rather misleadingly known by the name of the chemist or physiologist who introduced them. For easy reference to these Professor Tognoli's little book will be found useful, especially as Mr. Mitchell has added the names of some important reactions not included in the original.

Materia Medica, Pharmacy, Pharmacology, and Therapeutics. By W. HALE WHITE. Sixteenth edition. London: J. and A. Churchill. 1918. Pp. 716. Price 7*s.* 6*d.* net.—It is fortunate that the continued sale of this essential handbook, even in war-time, has made it possible to bring out a new edition, dated ahead, and incorporating in an appendix the various official regulations incident to war-time prescribing. These deal chiefly with the use of sugar and glycerine in medicines, the prescription of cocaine and other habit-producing drugs, and the substitution of corn starch for that from other sources. The book is a safe guide to war-time as to peace-time practice.

Diseases of the Stomach, Intestines, and Pancreas. By ROBERT COLEMAN KEMP, M.D., Professor of Gastro-intestinal Diseases at the Fordham University Medical School, New York. Third edition. London and Philadelphia: W. B. Saunders Company. 1917. Pp. 1096. Price 30*s.* net.—In reviewing the second edition of this large book we called attention to its essentially practical nature and the large amount of useful details in diagnosis and treatment. This feature has been borne in mind in preparing the present edition, and especially the effects of X ray diagnosis in gastric, duodenal, and gall-bladder conditions. Other important additions are in the sections on hyperchlorhydria and obesity. Abundant charts and illustrations are given.

Formulary of Certain Drugs used in the Surgical Treatment of Tropical Disease. Compiled by T. F. G. MAYER, M.R.C.S. Eng., Senior Medical Officer, Sierra Leone. Freetown: At the Government Press. 1917. Pp. 106.—This is a useful little compilation from the pages of current medical periodicals and works of reference, and will meet the needs of the practitioner in the tropics who has not the necessary works at his hand. The Formulary is arranged alphabetically, beginning with acetyl-*p*-aminophenyl stibiate of sodium and ending with zinc chloride, convenience of reference being assured by separate indexes of actions, authorities, and diseases. While the information itself is commendably exact, great liberty is taken with authors' names, a large proportion of which are misspelled—e.g., Dufreane, Leishmann, Erlich, Morrison, Haffkein, and it is this kind of petty annoyance which may mislead the reader into concluding a more general inaccuracy. But the only formula we have found at fault—among very many—is CH_4O for formaldehyd.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XXXVII. Session 1917. London: J. and A. Churchill. Price 12*s.* 6*d.* net.—Along with a number of valuable clinical papers, some of which have appeared in THE LANCET, this volume contains a verbatim report of the important discussion on the employment of the blind, which is very timely in appearance in view of the public action which is in prospect.

A German-English Dictionary for Chemists. By AUSTIN M. PATTERSON, Ph.D., formerly Editor of *Chemical Abstracts.* London: Chapman and Hall, Limited. 1917. Pp. 316. Price 9*s.* 6*d.* net.—Dr. Patterson has had excellent opportunities as an abstractor to make a thoroughly useful dictionary and has known how to use them. His book is concise and easy of reference, and, as far as we have tested it, both exhaustive and accurate. Not the least useful part is the preface dealing with the differences of chemical nomenclature in English and German, and the method of dealing with difficulties of terminology. The dictionary should be in the hands of every serious chemical student.

Ligations and Amputations. By A. BROCA. Translated by ERNEST WARD, M.D.Camb., F.R.C.S. Eng. With 510 illustrations. Bristol: John Wright and Sons, Limited. 1917. Pp. 282. Price 8*s.* 6*d.* net.—Professor Broca's work on the technique of amputation is sufficiently well known to need no mention, and Mr. Ward has done well to make it accessible to English readers. The translation is clear and precise and quite worthy of the text and the admirable illustrations.

Origenes y Tendencias de la Eugenia Moderna. By JOAQUIN BONILLA. Liverpool: *Daily Post* Printers. Pp 96. Price 3*s.* 6*d.* net.—This little book, written in Spanish by the Consul of Honduras, summarises the history of eugenics from the Greek philosophers down to Mendel and Sir Francis Galton. The author deals with the conditions brought about in this country owing to the war and with their solution in the light of modern teaching. The book is primarily intended for Latin America, but will be read with interest in this country.

JOURNALS.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Cambridge University Press. Vol. LI., No. 6. Pp. 347–468. Price 9*s.*—The Metabolism of Arginine, by W. H. Thompson. This is the fourth contribution by the author on this subject and deals with the effects on the excretion of total creatinine in the urine; of (1) arginine given in combination with methyl-amino compounds, and (2) of certain substances known to be methylated in the animal body. The author's summary alone runs to over two pages, so we must refer the reader to the original paper.—Observations on Degenerated and Regenerated Muscle, by J. N. Langley. The observations were made on cats chiefly from the point of view of changes in muscle weight. The normal difference of weight of muscles on the two sides varied from 1 to 5 per cent.

The denervated soleus lost weight more rapidly and in regeneration it recovered its weight more rapidly than the other muscles of the leg. After compression of the peroneal nerve, even in three weeks, marked contraction was obtained on nerve stimulation. After nerve suture the recovery from atrophy was very much slower. The observation that irritability of regenerating nerve is low for galvanic as well as for induction currents was confirmed.—The Rate of Formation of Fibrin Ferment from Prothrombin by the Action of Thrombokinase and Calcium Chloride, by John Mellanby. The formation of fibrin ferment in this way proceeds in a manner similar to that in the activation of trypsinogen by enterokinase; the velocity of the change is small at the outset, but continues with a constantly increasing acceleration. Thrombokinase and the Ca ion hold a reciprocal relation to one another. Neither alone can activate prothrombin. The author suggests that the ultimate agent in the activation of prothrombin is the calcium ion. Pure prothrombin is not activated by calcium in any concentration, but prothrombin to which thrombokinase has been adsorbed becomes unstable in the presence of calcium salts in proportion to the number of kinase elements contained in the complex.—Reflexes Excitable in the Cat from Pinna, Vibrissæ, and Jaws, by C. S. Sherrington. From the sensitive mobile pinna of the decerebrate cat a number of pure reflexes can be elicited. The movements are protective of the pinna; some, the retraction and folding reflexes, seem directed against irritant touches—e.g., the settling of fleas—or against exposure to injury in fighting; others, the cover and head-shake and scratch reflexes, against the ingress of foreign matter—e.g., dust, water, insects into the meatus and its ampulla. The mechanical threshold for their elicitation is extremely low, while with the exception of the scratch reflex they are elicited with difficulty and uncertainty by electrical stimuli. The reflexes, although connected eminently with the hairs, are connected also with other skin receptors separate from the hairs. Some of the stimuli may be thermal. The afferent nerve fibres concerned with each of these reflexes are supplied by several segmental nerve roots. As a group the reflexes are subserved by the trigeminus, vagus, and first, second, and third cervical nerves. The superciliary vibrissæ evoke reflex closure of the eye; the maxillary vibrissæ evoke no reflex in the decerebrate preparation. Mechanical and electrical stimulation of the gum, teeth, both maxillæ and mandibles, and front part of hard palate evoke opening of the jaws, followed by rebound closure. The reflex is preponderantly unilateral. There is a large representation of the jaw-opening and superciliary reflex in the cortex cerebri, but no evidence of any cortical representation of pinnal reflex movements. All the reflexes are easily obtainable under narcosis. The pinnal and superciliary reflexes are readily obtained in the normal animal.—X-Acid as a Remedy in Polyneuritis and Beri-beri, by D. T. Hulshoff. Although beri-beri may not be a neuritis in the strict sense of the term, it depends upon a degeneration of the nerve fibres. In fowls polyneuritis can be cured by the administration of a small bean—*Phaseolus radiatus*. The author attempted to isolate the active principle. He found a crystalline acid which he regards as the active principle, but as its constitution is unknown he has called it X-acid. Fowls with polyneuritis were fed with dry extract of the bean dissolved in water, and this sufficed to cure the disease.—On the Reaction of the Blood in the Body, by T. R. Parsons. Under equilibrium conditions the hydrogen-ion concentration of blood as measured electrometrically is the same as that of its plasma. The red corpuscles play a large part in determining the ionic equilibrium in blood; the changes in reaction produced in blood plasma by increase of CO_2 tension are much greater than those produced in the whole blood. An increase of the relative number of red corpuscles to the extent observed in pathological conditions exerts an appreciable effect on the reaction of the blood in the body, and so on the respiratory equilibrium. The effect of oxygen in expelling CO_2 from blood is due to the increased acidity it produces. Carbon-monoxide, like oxygen, increases the acidity.—Some Actions of Adrenalin upon the Liver, by F. A. Bainbridge and J. W. Trevan. Adrenalin, when injected slowly and continuously into the blood stream, leads to obstruction of blood flow in the liver, and if the obstruction is prolonged the general circulation becomes profoundly modified and a condition of "shock" results. Anæsthetised cats and dogs were used, the blood pressure being recorded from the splenic and iliac veins and the volume of the liver by recording the volume of one of its lobes in a suitable balloon containing water. The observations of previous experimenters were confirmed as to the injection of adrenalin into a systemic vein or into a tributary of the portal vein in causing a rise of pressure, increase of volume of the liver, and an increased lymph flow from the thoracic duct with little or no alteration in the vena cava pressure; and these effects are equally well produced whether the hepatic artery is intact or ligatured. They are due to the setting up by adrenalin of some obstruction to the flow of blood from the liver into the systemic circulation. Constriction of the radicles of the portal vein may be a contributory factor to the rise of the portal pressure, but the most probable cause is narrowing of the capillary channels by swelling of the columns of liver cells.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. XI., No. 41. October, 1917. Oxford: At the Clarendon Press; London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription price, 25*s.* per annum. Single numbers 8*s.* 6*d.* net each.—The contents of this number are: 1. Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis, by W. Parry Morgan. The mode of action of this form of treatment is critically considered. It is suggested that it is possible to obtain good results by partial instead of complete collapse, and that the method of partial collapse can be applied to both sides at the same time. Dr. Parry Morgan is of opinion that partial collapse of a tuberculous lung tends to give rest to any consolidated portion and thereby to reduce auto-inoculation. He also states that a moderate degree of collapse does not materially interfere with respiration provided it allows sufficient normal tissue to function. As a rule he has injected about 300 c.c. at the primary operation, and if no difficulty is experienced on the first side he has proceeded to inject a similar amount on the other side, at the same sitting in cases where bilateral collapse has appeared to be desirable. Afterwards at intervals of a week to a fortnight he has given up to 500 c.c., provided it did not produce a positive pressure. He has not gone on with the treatment for more than two or three months. He suggests the use of a rather more elaborate apparatus than that usually employed, a description of which has already appeared in THE LANCET.[1]—2. A Simple Rapid Method of Estimating the Filtrate Nitrogen in Small Quantities of Blood and of other Body Fluids, by R. Donald. The importance of an estimate of the nitrogenous waste in the blood in the diagnosis and treatment of certain diseases, especially those of the kidney, is emphasised and a practical rapid method for laboratory use is detailed. Briefly stated, the method consists in precipitating the proteins, centrifuging instead of filtering, and then testing the clear centrifugate by an efficient hypobromite process.—3. Experiments with Cholæmic Red Cells and Normal Red Cells in the Production of a Hæmolytic Immune Body in the Rabbit, by Leonard S. Dudgeon.—4. A Method of Estimating the Vibratory Sensation, by J. L. M. Symns. A special tuning-fork and the method of using it are described. Records with charts of illustrative cases are given. Dr. Symns concludes that when the vibratory sensation is diminished over the sacrum, the disease involves the spinal cord; when it is impaired over one or other extremity, the disease involves the peripheral nerves only; while if it is general it indicates a systemic poisoning. Discussing the nature of the vibratory sensation, he suggests that it is dissociated from the sensations of pain and temperature, and that it appears to be a mixed sensation and closely allied to "deep sensibility."

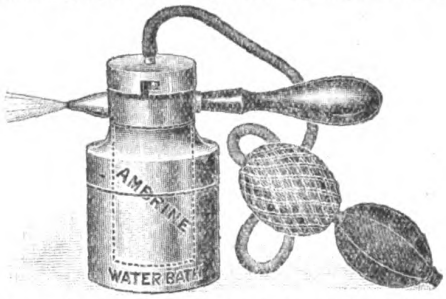
"Semprolin" Emulsion with Iron

THIS preparation admits the administration of iron *for long periods* without digestive disturbance or constipation. The iron, being in colloid form, is quickly and easily assimilated. With Liquid Paraffin no habit is induced as with purgatives such as cascara, aloin, &c. Gives excellent results in Anæmia, &c.

In 8-oz. and 16-oz. Bottles.

CONTAINING

Dialysed Iron ... ... 20 minims
Russian Liquid Paraffin, B.P. 55%
in each tablespoonful.



Samples Free to MEDICAL MEN

Hyperthermal-Therapy.

AMBRINE

Ambrine is *the only Authorised preparation* of Dr. Barthe de Sandfort. We are compelled to state this, as there are various imitations.

May be applied with camel-hair brush, but our specially designed spray greatly facilitates the application of Ambrine, especially in the case of deep wounds or extensive surfaces.

Ambrine forms a dressing which INSTANTLY alleviates pain—promotes rapid healing—forms a sure protection against infection of the wound—can be removed without pain, hæmorrhage, or injury to the newly-formed tissues. The healing leaves no scars or contractions.

The most efficient means and method of ensuring active **Hyperthermal-Therapy** to the practical treatment of **Rheumatism, Gout, Arthritis, Varicose Ulcers,** and similar affections.

26-10 17.

SIRS,—I thank you for sending me the Ambrine; I found it very effective in a chronic and painful varicose ulceration of the leg. Please send another 5s. worth. (Signed) A. G. W——, M.D.

The Treatment of CARBUNCLES, BOILS, ANTHRAX, ACNE, STYES, and Diseases arising from Staphylococcus.

STANNOXYL

(An Oxide of Tin and Tin Metal Free from Lead).

A scientific production the value of which has been studied very closely. The effect is very prompt; from the second day of treatment the pain is relieved, the carbuncles begin to dry up, and those which are just opening are stopped in their course; the core is not expelled but reabsorbed.

In the majority of cases definite results are obtained within five or six days; it is seldom necessary to take the full ten days' treatment, and relapses are unknown.

The daily dose for adults is 4 to 8 tablets: children 2 to 4 tablets.

Supplied in vials of 80 tablets.

LITERATURE and CLINICAL REPORTS on REQUEST.

Medical Treatment of CANCER.

CUPRASE

Cuprase is a colloidal Copper hydroxide which is obtained chemically by the reduction of Salts of Copper in the presence of Albumosic Acid.

The numerous clinical reports from Doctors of repute in various countries give cases of a great variety. In all of these **pain has been eliminated,** and in a good percentage **cures are claimed,** and in no instance **any undesirable** effects.

Its *easy application* (subcutaneous injections) places it within the reach of all practitioners. It *is not toxic.*

Disappearance of the Pain.

Return of Sleep.

Increase of Appetite,

Colour and Strength.

WARWICKSHIRE, July 1st, 1917.

DEAR SIRS,—Will you please send me another box of Cuprase ampoules. The previous lot effected a most remarkable cure in an elderly lady suffering from cervical cancer—the cauliflower-like growth has disappeared with its offensive discharge.

This case was given three months' life by a Specialist, being inoperable.

Yours faithfully,

(Signed) B—— B——, M.R.C.S., L.R.C.P.

THE LANCET.

LONDON: SATURDAY, DECEMBER 29, 1917.

Fresh Light on Tetanus Problems.

AT a recent meeting of the Society of Tropical Medicine Professor WILLIAM BULLOCH described tetanus as a disease in the clinical knowledge of which there has been no advance since the time of Hippocrates, and he went on to marvel that 20 years after the introduction of antitoxin treatment its value to the patient should still be under discussion. This breezy reproach is being removed by the War Office Committee under the chairmanship of Sir DAVID BRUCE, whose fifth analysis of cases of tetanus treated in home military hospitals we published last week, and at whose instance we have been able to publish in this and in the preceding issue of THE LANCET a further series of valuable contributions to the study of tetanus from many points of view.

Statistically, what is to be said can be said briefly. Captain H. GREENWOOD admitted, in the debate at the Society of Tropical Medicine, a high degree of association between the use of prophylactic inoculation and the lengthening of the incubation period. Tetanus that takes long to develop, as a rule, gets well, and there is no need to look about for any other explanation of the diminished fatality than the prophylactic use of serum. But the association between large therapeutic doses of serum and the recovery-rate is not at all of the same order, and Sir DAVID BRUCE himself concludes that in regard to the therapeutic effect of antitoxic serum the evidence is still inconclusive. Prevention is, of course, better than cure, and in no disease more abundantly better than in tetanus, but the proportion of wounded men who continue to develop the disease in home hospitals is still put down at about 1 in 1000, and with the enormous size of the armies engaged the absolute number of cases of tetanus remains sufficiently serious to make a problem of first-rate importance. Prophylactic injection, besides so notably diminishing the number of cases requiring therapeutic injection, has also produced a new form of tetanus, the study of which is greatly adding to our store of useful knowledge. The facts of local tetanus have already brought Dr. FRED RANSOM to the view that tetanus toxin does not enter the central nervous system by the lymphatic or blood channels, but passes exclusively along the motor nerves and through the protoplasm of the neurons themselves. The toxin in nerves and nerve cells is inaccessible to antitoxin. Antitoxin is transported by the lymph and blood; it is not taken up by the nerves, and there is no reason for thinking that it ever reaches the nerve cells. This appears to agree with the clinical facts in man, although not quite consistent with the experimental results obtained by Professor C. S. SHERRINGTON with antitetanus serum on monkeys. Using a dose of 2 mgm. toxin per kilo. of monkey and following this dose up after a period of from 47 days upwards by an injection of 2000 U.S.A. units of antitoxic serum per kilo. of monkey, Professor SHERRINGTON was able to save the lives of 2 out of 25 monkeys by the subcutaneous route, 3 by the intramuscular route, 7 by the intravenous, and as many as 14 by the lumbar intrathecal route, and finally 13 out of 20 monkeys were saved by bulbar intrathecal injection. It would seem that under experimental conditions toxin which is already firmly united to nerve cells can be detached by a sufficient concentration of antitoxin in the surrounding lymph spaces. Some new examples of the fixation by nerve cells of various stereoisomerides were given last week in a summary of a lecture by Dr. F. L. PYMAN and may be read in this connexion.

The other articles in the tetanus series all contain observations of practical significance. Dr. N. A. COOPER'S account of more than 100 consecutive cases of tetanus in civil practice in India is useful as a control, inasmuch as there was in no case any chance of using antitoxin as a prophylactic. Many of his cases, too, had no external evidence of injury. Captain F. GOLLA'S lucid analysis of recent tetanus statistics gives the basis of mortality from the disease in pre-serum days and affords a further useful criterion for comparison. His figures also confirm the view that, apart from prophylaxis, serum treatment has so far not been shown to exert any influence on mortality. Captain R. N. SALAMAN'S notes on 10 cases illustrate the value of a particular sign—the loss of the swinging movements of the jaw—in the diagnosis of the developing disease. And, finally, Captain H. BURROWS'S interesting case of splanchnic tetanus is a further illustration of Dr. RANSOM'S view that tetano-toxin combines with any nerve cells with which it comes in contact, and that its apparent preference for the motor neuron is only accidental, inasmuch as it is to the muscles that the tetanus bacilli gain access in gunshot injuries, whence the toxin passes up to the motor nerve cells. Systematic combined work of this nature is rapidly removing Professor BULLOCH'S reproach and will, we hope, soon lead to an increase in our knowledge of tetanus which will exert a beneficial effect on its treatment.

The Care of the Pregnant Woman.

AT the present time, when we have to consider not only the falling birth-rate—common as it is to almost all the civilised nations of the world—but also the terrible loss of life among the younger and more virile members of the communities which are now plunged in grimmest struggle, it is impossible to exaggerate the importance of conserving the health of the expectant mother and her unborn child. The matter is one which is now attracting much attention, and steps are being taken in many of our large cities and in many rural districts to extend or to initiate this branch of preventive medicine. It is evident, however large a part is

played by heredity, that improved health cannot fail to be of benefit to the babe while still within the mother's womb. And it is difficult to realise how little, until comparatively lately, has been done in this direction, how many thousands of women pass through the whole of their pregnancy without once seeing or consulting their doctor, and how few medical men realise to the fullest extent what can be accomplished by antenatal care and treatment. For there are many measures which may be taken to ensure the health of the unborn infant, and to safeguard the mother from the perils which may beset her during the nine months of her pregnancy, a time when indiscretion or want of care may endanger not only her own life but also that of her baby.

We must admit that our knowledge of many of the problems of antenatal pathology is very scanty, but it is a fruitful field for investigation, and, without doubt, research in this direction, which will be much more possible in the near future than it has been ever before, will yield abundant results. The interest awakened on the part of the public generally in these matters has been very marked recently, and Maternity and Child Welfare Centres are springing up all over the country. These agencies are performing a very valuable work not only in educating young mothers in the proper care of their infants but also in encouraging them to seek medical advice as a routine measure at an early period of their subsequent pregnancies. When every expectant mother realises that it is not fair to herself, to her unborn child, or to her doctor, to withdraw herself from skilled supervision at all during her period of gestation, a very large step forward will have been taken in the promotion of preventive midwifery. It can be asserted truthfully that if every woman were compelled to enter a lying-in hospital for her confinement some thousands of lives would be saved in the United Kingdom every year as a result of the almost total abolition of the risk from puerperal sepsis; and similarly if every woman was compelled to place herself under the care of a doctor during her pregnancy the death-rate from the toxæmias and accidents of childbirth would be greatly decreased. It is a sad reflection to make that in this country more care is bestowed as a rule upon a thoroughbred mare when in foal than is bestowed upon the great majority of expectant mothers. It has been stated that "it is more dangerous to be a baby in London than a soldier in the trenches," but we may look forward to the time when it will be impossible to level such a reproach upon the nation, for the death-roll among infants is in reality the concern of every one of us. It is impossible to imagine that such a state of affairs will be allowed to continue in the better appreciation of the value of infant life which is becoming so widespread.

In a Presidential address delivered before the Royal Academy of Medicine in Ireland, Professor ALFRED SMITH advocates the establishment of what he terms expectant-mother hospitals and their endowment by the State. In the event of mothers being unable to enter such a hospital, he suggests that they should attend special dispensaries for advice and any necessary treatment. It is questionable whether it will ever be possible to get mothers among the poorer classes to enter such hospitals in any large numbers, and we are inclined to believe that a more general establishment of the maternity centres now in operation would meet the case to a large extent. At these centres the mothers can be watched and supervised, their health when necessary attended to, and their home conditions investigated and dealt with by the visitors working in association with the centre. The development of these centres, with the addition of pecuniary means for providing necessitous cases with proper food and, if necessary, whatever may be required at the time of the confinement, is even now making great progress, and in many of the larger hospitals at any rate there are beds available for any pregnant women who require special care or treatment. It would be impracticable to provide such hospitals for any very large number of expectant mothers, but the provision of well-equipped maternity and child-welfare centres all over the country, assisted if necessary by State funds, should be quite a feasible matter. It would not be a difficult thing in the course of time to persuade every woman to register her pregnancy at such a centre.

Annotations.

"Ne quid nimis."

THE PHYSICAL BASIS OF GENETICS.

To the average hearer the expert is never so interesting as when he comes out of *expertise* and makes contact with the world beyond his particular specialty, and Professor W. Bateson's lecture at the Royal Microscopical Society last week had the special interest of a borderland subject. Reviewing the newer American researches in cytology, Professor Bateson discussed how far these might be taken as forming a material basis for the well-known facts of genetics. The assumption that it is the individual chromosome which carries on a particular character from germ cell to germ cell is, of course, untenable, as there are far too few chromosomes in a nuclear skein for each to be the bearer of a single discontinuous characteristic. But Professor Bateson agreed that the American observers were well within their rights in associating the number of chromosomes with the inheritance of groups of characters—so-called linkage—although himself believing that there was some more ultimate physical basis common to both inherited character and nuclear filament. Many of the points which he made easily elude the mind when freed from the lecturer's personal magnetism, and from the hypnotic effect of genealogical tables and charts of Mendelian characters, and one of the practical deductions may be cited. Professor Bateson regards it as proven that in the inheritance of colour-blindness the male element must be taken as determining the sex. The spermatozoa, he concludes, are predetermined as male or female quite irrespective of the influence of the ovum they are to fertilise, whereas the converse is true in certain well-known instances in the animal kingdom. In the animal kingdom an extra, the so-called X-chromosome, has been shown to be present in the predominating

sex-element. Presumably the same also holds in man. At the close of his lecture Professor Bateson paid a generous tribute to the work of protozoologists and expressed a hope, which we share cordially, that a more coördinated study of genetics and protozoology will lead to the solution of some of the basic questions now at issue.

THE ADMINISTRATION OF LARGE DOSES OF QUININE BY HYPODERMOCLYSIS IN THE TREATMENT OF MALARIA IN TROOPS.

Professor U. Pende, of the University of Palermo, has used for more than ten years a method of treating malaria which he strongly recommends as effecting both a "therapia magna sterilisans" and an economy in the use of quinine. Subcutaneous or intramuscular injections have frequently failed to triumph over the infection even in doses of one gramme repeated daily for 20–30 days, whereas Professor Pende's method, which has nothing to lose in comparison with the intravenous by way of rapidity and certainty of action, has the advantage of being able to introduce into the circulation a larger quantity of quinine without any danger, and thus of paralysing to the utmost the vitality of the most resisting forms of parasite, even when entrenched in the depths of the various viscera.

The method consists in a hypodermoclysis, repeated every 5–6 days for 4–5 times, of 250 grammes of physiological salt solution, to which are added 2 grammes of bihydrochlorate of quinine, and half a cubic centimetre of 1 in 1000 solution of adrenalin. The technique is very simple, the middle of the anterior external part of the thigh being selected as the most favourable site for the injection, the fluid being held about 6 feet above the ground penetrates the tissues in 10–20 minutes and causes no pain; absorption is rapid, as the drug can be detected in the urine about an hour afterwards. The first injection is given, if possible, 6–7 hours previous to an attack and is followed by a second in 15–24 hours; on the fifth to sixth day a third is given, and after a further 5–6 days, a fourth, always in the same dose of 2 grammes, equivalent to 1·60 grammes of pure alkaloid. A week after the fourth injection quinine is given by mouth in doses of 2–3 grammes a day in 6–9 powders, for two days in succession every week for a couple of months, arsenic and iron being given on the intervening days. The effect of the treatment is that in the majority of cases the temperature falls completely, sometimes with a rapidity very striking in severe forms which have resisted previous treatment by quinine by the mouth or ordinary hypodermic injection. Sometimes there is a modified abortive attack one or two days after the second hypodermoclysis, followed by complete apyrexia. After about three months a perfect clinical cure results.

Professor Pende considers that the results would be still better, and reduce to the minimum the probability of relapses, if the treatment could be always applied in the initial attacks of a malarial infection—that is, before the formation of quinine-resisting gametes. There appear to be no contra-indications to these heroic doses of quinine in subjects free from organic disease of the circulatory system or kidneys. No traces of albumin are to be found in the urine, while the addition of adrenalin serves to counteract vasomotor collapse which might be apprehended from such large doses of the alkaloid in subjects specially predisposed to vascular atony.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE next annual Congress of the Ophthalmological Society of the United Kingdom will be held under the presidency of Mr. E. Treacher Collins, secretaries, Mr. S. A. Kinnier Wilson and Mr. M. S. Mayou, on Thursday, Friday, and Saturday, May 2nd, 3rd, and 4th, 1918. On Thursday, May 2nd, meetings

THE CONTROL OF VENEREAL DISEASES.

Venereal Disease in the U.S. Army.

A RECENT meeting of the College of Physicians of Philadelphia was entirely devoted to a discussion on the control of venereal diseases under the new conditions consequent on military mobilisation in the United States. Colonel T. H J. C. Goodwin, A.M.S., opened the debate with an account of the venereal campaign being carried on in this country, emphasising the fact that during active service the diseases are more adequately dealt with than in time of peace. Major W. F. Snow, of the U.S. Medical Reserve Corps, spoke of the authority given to the Secretary for War over the zones surrounding military camps. Every effort was being made to obtain the "social facts" from infected soldiers in order that "carriers" might be traced. Colonel F. F. Russell, of the U.S. Medical Corps, who has been commissioned by the Surgeon-General to organise the preventive side of anti-venereal measures, stated that the third week of the draft army showed an "astonishing increase" in the number of cases of venereal disease. He added: —

"Whether this means that these diseases are much more common among young men of military age in the civil population than we ever supposed I do not know. Certain it is, however, that we have almost 400 per 1000, whereas our highest rate in the last 20 years in the Army has been 162. . ...

We shall institute early treatment of venereal infection by all the so-called prophylactic methods, if possible, within a few hours of exposure. We shall make frequent inspection of the troops to discover concealed cases. We shall penalise a man who develops venereal disease by taking away his pay and his liberty until he is cured. If he develops venereal disease and does not avail himself of the facilities of treatment he will in addition be court-martialled, and if found guilty he will be placed in confinement at hard labour."

Colonel Goodwin spoke of venereal disease as being the commonest cause of invaliding in the U.S. service, others being in order of frequency: tonsillitis, influenza, bronchitis, diarrhœa and enteritis. Other speakers emphasised the crucial value of education and recreation. Mr. G. W. Braden, of the Central Y.M.C.A. of Philadelphia, quoted the fact that on the Mexican border, when the men were kept busy with wholesome games and amusements, the number applying for prophylactic treatment was very low, and Colonel Goodwin confirmed this view from experience of the Y.M.C.A. in this country.

The Teaching of Sex Hygiene.

Sir Thomas Barlow's address at the Annual Meeting of the Incorporated Association of Headmasters has been published in pamphlet form (price 2*d.*) by the National Association for Combating Venereal Diseases. The announced title of the address, The Teaching of Sex Hygiene, was widened to The Incidence of Venereal Diseases and its Relation to School Life and School Teaching, in order to give the speaker the opportunity of putting the headmasters present in possession of all the aspects of the subject which he thought would be useful to them. He spoke of the relatively high death-rate from syphilis among the upper and middle classes as compared with miners, textile workers, and agricultural labourers, and said that in some military camps officers had encouraged their men to enjoy themselves sexually when they had a chance. Sir Thomas Barlow then emphasised the need for self-control and a high moral tone throughout schools; no boy, he said, should be admitted to a public school unless the master had been informed how far the boy had been warned against masturbation, or until the boy had overcome the habit if acquired. To the boys leaving school he thought it was expedient not only to explain the value of continence but to make them understand the function of the testicles in supplying an internal secretion contributing to the energy and vigour of youth. The risk of acquiring sexual disease ought to be mentioned, but to normal boys was less effective as a deterrent than other arguments. He spoke of the value of a course of school lecture demonstrations on the principal facts of animal economy, but, in common with Huxley, would leave out the sexual organs in the first course. Sir Thomas Barlow's thoughtful and stimulating address will have interest for school doctors as well as teachers. Mr. Stephen Paget's lecture on Adolescence, in the Sheldonian Theatre, to Oxford University Extension Students has also been printed (London: Constable and Co. Price 7*d.*). So far, he says, as adolescence is concerned, if ever there was a time when we ought to speak plainly it is now. Whether we like it or not, the old habit of silence has for some years been falling away from us. What children need, however, is not physiology alone, but physiology and faith together.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Anti-Malarial Measures in Bengal.

THE Governor of Bengal has visited parts of the province to see for himself the nature of the anti-malarial measures being carried out. Malaria is very prevalent on the banks of the Ganges all the year round. The object of the measures adopted is to reduce the breeding places of mosquitoes to a minimum by turning the low-lying area into a single sheet of water at intervals during the flood season, and by draining it thoroughly both at the beginning and at the end of the rainy season.

The Blind of Bengal.

The report of the Calcutta Blind School for the year 1916 shows that 1916 is one of the most memorable years in the annals of the blind in India. It has witnessed the introduction of easy rates for "blind literature" packets by the Indian Post Office, the formation of an Association of Workers for the Blind in India, the publication of a magazine in Mysore in the interests of the blind called the *Light to the Blind*, and, most important of all, the issue of a circular by the Government of India on the question of the education of the defectives. During the year the Government of India also raised the question of teaching Indian soldiers who have returned totally blinded from active service some trade by which they could earn a little money with which to supplement their pension.

Public Health in Bombay.

Dr. J. A. Turner, the executive health officer to the municipality, in presenting his seventeenth annual report, states that, considering the circumstances and conditions prevailing, the health of the city of Bombay during 1916 has been extremely good, though not quite so good as in the exceptional year, 1915. At the same time he admits that, except in one or two matters of detail, little progress has been made in improving the sanitation of the city; this has been due to financial stringency on account of the war. The population in 1911 was 979,445, and on this census the sickness and mortality ratios have been calculated. The total death-rate was 31·21 per 1000, a reduction on the quinquennial average of 32·92 for 1911-1915, and lower than in any previous year except 1915, when the quite exceptional ratio of 24·17 was recorded. The death-rate for males (27·56 per 1000) was, as always, much lower than that for females (38·11), being largely to be accounted for by the preponderance of males, who form nearly two-thirds of the population. Hindus of various castes number 684,502, with a death-rate of 30·65; for Mussalmans the ratio was 36·91, for Parsis 19·22, and for Europeans 33·88 (in a population of 11,894). The infant mortality ratio (per 1000 births) was 387·8, being higher than in the three preceding years; about two-thirds of the births occur in tenements of one room, and with these infants the mortality ratio was 454 per 1000; in tenements of four or more rooms the ratio was 238, and among infants born in hospital not more than 92 per 1000. The municipal nurses and health visitors of the Sanitary Association and of the scheme started by Lady Willingdon, who are all qualified midwives, continue to do much good work in the prevention of disease and in the nurture of infants: there are three maternity homes for the poor, two new ones having been opened in 1916, and others being in course of formation; these homes are visited regularly by members of the Ladies' Committee; the health officer states that it is impossible to over-estimate the very valuable work which is being done in this direction, and which gives promise of further development. The mortality from epidemic disease per 1000 was higher than in the exceptional year 1915, but lower than in the decennium (1906-1915); small-pox caused 1021 deaths (1·04 per 1000), being considerably in excess of the decennial average (0·52); otherwise the figures show an improvement on the whole, except in the case of plague, which caused 1987 deaths (2·02 per 1000), more than three times the number of deaths in the preceding year, which, however, had been the lowest on record. Rat destruction was carried out vigorously, 943,346 having been collected and destroyed; nearly half of these were bacteriologically examined, the percentage found infected being 2·54, an increase on the percentage of infection (1·57) in 1915; in March the infected percentage was 6·57, and in April 7·30; the plague deaths in these two months were in the ratios of 6 and 8 per 1000 respectively. Wherever a case of plague occurred, or an infected rat was found, the place was treated with preventive

together with all the passages and gullies in connexion; 22,000 rupees were expended on disinfection by this and other disinfectants. Small-pox was more prevalent than in the preceding year and in the decennium: there were 1021 deaths, double the decennial average (511). Cholera caused 141 deaths, and prevailed throughout the year, though not with epidemic intensity. Tuberculosis continues to be both prevalent and fatal, having caused 1902 deaths (1·94 per 1000); this is higher than in the previous year (1·74), but less than the quinquennial average (1911–1915) of 2·29. A special inquiry was conducted as to its incidence; it was found that the Telugu community were highly infected, especially among women working under most unhygienic conditions. Owing to a severe outbreak of small-pox the Arthur Road Hospital was converted into a special hospital for this disease in April and May; afterwards cholera cases were admitted. The small-pox statistics at this hospital now extend over 29 years, embracing 10,393 cases; Dr. N. H. Choksy, who has been connected with this work throughout the whole period, points out that the case mortality for the vaccinated has averaged 15 50 per cent., for the unvaccinated 35·30 per cent.; the mortality among the latter was more than twice that of the former, although many of these were but imperfectly protected. A valuable series of cholera cases treated at the hospital from 1893 is also tabulated by Dr. Choksy; for the period 1893–1904 the recoveries were 25 per cent.; in the five years, 1905–1909, they average 47 per cent.; for 1910–1912, 52·30 per cent.; and for 1913–1916, 67·30 per cent. In this last period the treatment has consisted in subcutaneous injections (one to two pints of hypertonic saline) for all grave cases of collapse, and rectal injections in comparatively milder cases, supplemented by pituitrin, atropine and caffeine, or theobromin sodium salicylate, as required. Dr. Turner's report is full of interest and is supplemented by numerous detailed tables and a map.

Small-pox in Burma.

The Sanitary Commissioner of Burma in his latest report points out that small-pox is brought into Burma chiefly by sea, and that epidemics in India are generally followed by an outbreak in Burma. Rangoon is never free of small-pox, but the disease is kept in check by efficient vaccination.

Burma Medical School.

Chinese and Indian residents of Rangoon have subscribed to a fund for awarding prizes to successful students at this school. The Inspector-General of Civil Hospitals, Burma, and the Secretary to the Government of Burma have been appointed trustees of the fund.

Charitable Dispensaries in the Punjab.

The Inspector-General of Civil Hospitals of the Punjab estimates that at least 93 new dispensaries are required. But even with the contemplated additions there will be on an average no more than one dispensary for every 35,000 persons in the province, and it has to be remembered that the radius of influence of each institution is necessarily limited, and that there is no class of scientifically trained rural practitioner to whom the villager living remote from the nearest dispensary can turn for relief in his sickness.

Women's Work in India.

A women's registration bureau has been started in India to enable every woman to take a share in war work of some kind or other. In this relation the Lieutenant-Governor has issued a letter to all the commissioners and heads of departments at the request of the Commander-in-Chief in India appealing for assistance in obtaining the services of a certain number of hospital visitors and V.A.D. nurses who have passed the necessary tests for auxiliary service in station hospitals in Burma.

Military Sanitation in India.

It is officially announced that a standing sanitary committee will be formed in each division to consider and report on measures likely to conduce to an improvement in the health of the troops, both British and Indian, in cantonments, and to assist the Divisional Commander in initiating proposals for such measures.

Appointments in India.

Captain P. M. Rennie, I.M.S., having been posted to military duty, Major R. A. Needham, D.S.O., I.M.S., Assistant Director-General, I.M.S. (Stores), is appointed health officer, Simla, in addition to his own duties.

THE King has appointed Mr. Hugh Mallinson Rigby, surgeon to the Household, to be one of his Honorary Surgeons.

BY will the late Mr. Alexander Grant-Meek, of Devizes, and Lord of the Manor of Manningford Bruce, has left £1200 each to the Devizes Cottage Hospital, the Royal Mineral Water Hospital, Bath, and the Savernake Cottage Hospital.

Correspondence.

"Audi alteram partem."

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

To the Editor of THE LANCET.

SIR,—The terrible plight of these poor Belgian doctors and pharmacists is well known to the members of the committee, and is vouched for by the touching letter from Mr. Poland in your issue of to-day. Some members of the profession have given with great liberality to the Fund, and some, under the impression, I have reason to believe, that there was no great need, have contributed small sums, but when the need was pointed out have increased their subscriptions. May I appeal to others to do likewise and to give as generously as they can. I enclose my cheque for £25.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 22nd, 1917. HERBERT R. SPENCER.

THE ADMINISTRATION OF BROMIDE.

To the Editor of THE LANCET.

SIR,—There is probably no drug in the Pharmacopœia more valuable than potassium bromide, and yet it is one that is constantly decried by some physicians. It has always appeared to me that the dislike to this drug was largely due to the erratic way in which it was administered. It is usually given in larger doses than are necessary, and in order to counteract its depressing effect a stimulant such as strychnine or nux vomica is prescribed with it. Why not give a small dose and avoid having to give an excitant which is usually directly harmful to the patient who is in need of the bromide salt?

For many years I have been prescribing potassium bromide in very small doses, and I have found a small dose such as 5 grains once a day long continued far more efficacious than larger doses for shorter periods. In functional nervous disorders, such as neurasthenia and nerve exhaustion, and in traumatic neurasthenia reflex irritability is one of the earliest symptoms, and as this irritability increases, so the personality of the patient becomes more and more disturbed. Now if it is possible to control this irritability, the patient may rapidly improve and may continue to work with comparative comfort. I have found from long experience that 5 grains of potassium bromide once a day will control this reflex irritability. The smallness of the dose avoids the depressing effect of the salt, and it may be taken with great advantage for many years during the active business or professional life of the individual.

On finding the value of these small doses in controlling hypersensitivity and irritability in adults, it occurred to me that still smaller doses might be of value in childhood, and the results obtained have been equally satisfactory. The excitable and irritable child wears itself out, and as it grows further nervous and mental symptoms develop. For example, many persons, including children, who develop epilepsy have passed through one or more years of increasing nervous excitability. Correct this irritability and the epilepsy is prevented. That this is true I have proved in many cases; for example, I have prescribed one daily dose of 3 to 4 grains of potassium bromide for a child whom I regarded as a potential epileptic, and gradually the irritability would disappear; the dose was then discontinued under the usual belief that it was harmful to continue for any length of time, and slowly the symptoms would recur and finally culminate in an epileptic seizure. A physician need have no hesitation in keeping an excitable or nervous child on a trifling dose of bromide throughout the greater part of his school days. The potassium salt is undoubtedly more efficacious than the other salts and is not depressing in small doses. It is true that some cases of nerve exhaustion require larger doses to begin with, but it should be the aim in these cases to reduce the dose as soon as possible and then continue for years if necessary. The reason I recommend continuing for years is that once a person suffers from nerve exhaustion he will always tend to get a recurrence of his symptoms with stress and mental strain, and I find that the small daily dose of bromide is a great protective. I have never known a person

suffer from taking bromide in this way, but, on the other hand, it is only too common to see patients suffering from the want of it.—I am, Sir, yours faithfully,

Harley-street, W., Dec. 17th, 1917. MAURICE CRAIG.

THE TREATMENT OF EXOPHTHALMIC GOITRE BY X RAYS.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 15th Lieutenant-Colonel T. P. Dunhill discusses the treatment of exophthalmic goitre from a surgical point of view. In the course of his paper—the fairness and courtesy of which might serve as a model in medical controversy—he makes the following remark:—

"It ought to be possible to obtain some unanimity of observation among men who are working along different lines to the same end. If experiences could be exchanged; if, above all, men of divergent views could see the same cases before and after treatment, or before and after operation, it should help."

As Lieutenant-Colonel Dunhill does me the honour to refer to me as one of the exponents of the X ray method of treatment, I think that perhaps a few comments on my part may help to bring nearer that mutual understanding for which he hopes.

In the first place, let it be said that the attitude of the surgeon and of the radiologist in approaching a case of exophthalmic goitre is essentially the same. Both admit the necessity of searching for ultimate causes; both know from experience that in the majority of cases, "the *manifestations* of Graves's disease are the manifestations of excessive and disordered functional activity of the thyroid gland." I say from experience, because the lessening of the amount of the thyroid hormone, either as a result of X rays to the gland, or from actual surgical removal of thyroid tissue, is nearly always followed by clinical improvement. Any difference of opinion is therefore limited to a consideration as to the best *method* of reducing the amount of secretion.

Before proceeding further, it is necessary to draw a sharp line of distinction between the *average* case and the resistant case. I use the word "resistant" rather than "severe" or "acute" because some of the most alarming cases readily yield to X rays, whereas now and then one of the more ordinary type fails to respond.

(1) When an ambulant case presents itself to the physician for treatment it is, of course, his duty to search for any possible cause and also to prescribe drugs, gland extracts, &c., according to his experience. He should also consider X rays, and, as an ultimate possibility, surgery. I do not think it will be claimed by anyone—certainly not by Lieutenant-Colonel Dunhill—that ambulant cases should be operated on forthwith. But is there any reason, apart from questions of convenience and expense, why they should not all be treated by X rays from the beginning? That X rays are beneficial is admitted by the highest authorities—e.g., by Professor Murray and Dr. Hector Mackenzie. Their use permits the patient to remain at work or play and does not in any way interfere with drug or hormone treatment. There is no risk of burning, and no attempt is made, in the *average* case, actually to destroy any thyroid tissue. To limit the activity of the gland, and at the same time to bring the type of activity back to normal, is the object aimed at. That, with the technique employed, no permanent deficiency of secretion results, is proved by the fact that the majority of cases are cured and remain healthy, while the remainder relapse into a hyperthyroidic state. That faulty methods may overstep the safe limit is true. The surgeon's knife in unskilled hands may slip. And the X ray tube is a subtle tool, calling for skill and experience in the user. But it remains broadly true that in the average case no risk is run, and that should an operation subsequently prove necessary its success will not have been in any way prejudiced by the X ray treatment. Especially is this so of late—within the past year—when the combination of the sinusoidal current with X rays has enabled us greatly to reduce the dose of the latter, without in any way interfering with efficiency as regards banishing symptoms, and with an improvement in the cosmetic effects.

The average ambulant case of exophthalmic goitre should receive X ray treatment from an early date. Definite improvement is often manifest within a month.

(2) *Resistant cases.*—These are cases which do not respond to the ordinary dosage of X rays, combined with other suitable medical treatment. The courses open are: (*a*) to increase the X ray dosage till it nears, or even reaches the sterilisation point; (*b*) to remove some of the gland tissue surgically.

The objections to (*a*) are that permanent thyroid feeding may be necessary, and that absolute safety to the skin cannot be guaranteed. As to (*b*) the drawback in the past has been the high mortality attendant upon the operation. No radiologist is anxious to treat such cases. If the operation mortality has been so reduced by recent improvements in technique as not to exceed that for, say, appendicitis then I, for one, am ready to retract what I have hitherto said about surgery in such cases and to recommend it. But I am firmly of opinion that few cases should need surgery if properly treated from the beginning. Ulceration of the cornea, visceral degeneration, and extreme emaciation ought never to occur. If suitable medical and X ray treatment does not produce definite improvement within a reasonable time operation should be considered, and this period should be reckoned by months rather than by years.

(3) There remains to consider briefly the case with acute onset, where the patient is bedridden from the start. Is such a case to be treated by setting up an X ray installation in the patient's house or by operation? Much will depend upon the stamina of the victim. If he is in no immediate danger of death, or if it is held that an operation would probably prove fatal, X rays are indicated. But immediate reduction of thyroid secretion can, of course, be secured only by surgery.

Lieutenant-Colonel Dunhill's paper was a fair and temperate statement from the surgeon's view-point. I trust these remarks by a radiologist may deserve the same epithets and may do something to bring about agreement rather than promote controversy.

I am, Sir, yours faithfully,

FRANCIS HERNAMAN-JOHNSON, M.D.

Harley-street, W., Dec. 22th, 1917.

CONGENITAL WORD-BLINDNESS.

To the Editor of THE LANCET.

SIR,—In the review of my book on "Congenital Word Blindness" in THE LANCET of Dec. 8th there is an error which I wish to correct. Your reviewer states: "He cites in some detail various cases of congenital word-blindness that have come under his notice, in one of which there is a report of the pathological condition." The report of the pathological examination thus referred to is on a case of *acquired* word-blindness, to which subject the first chapter of the book is entirely devoted; the report has nothing whatever to do with the cases of congenital word-blindness which are recorded in the subsequent chapters of the book. The insertion of these few lines in your columns will greatly oblige

Yours faithfully,

Mentone, France, Dec. 12th, 1917. JAMES HINSHELWOOD.

SUCCESS AND FAILURE IN THE TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Louis Cobbett acknowledges that he cannot by isolation even cut off one source of infection, therefore this measure alone is bound to fail in stamping out the disease. Nevertheless, I agree with him, as I have said, that isolation is necessary, and I have no doubt he will keep urging the authorities to establish the 500,000 beds that will be necessary in Great Britain and Ireland. The tubercle bacillus at any rate, produces a sufficient degree of immunity to enable at least 85 per cent. of those infected to recover without aid. Pneumococcic pneumonia does not confer a marked degree of immunity in those who recover from it—on the contrary; and yet preventive inoculation is stamping out pneumonia amongst the South African miners.

Dr. Cobbett's hopes for the continued decline of the death-rate from tuberculosis are shown to be chimerical by Karl Pearson's investigations. Those who think that the reduction in the decline of the tuberculosis death-rate is solely due to the war are deceiving themselves.

Finally, since Dr. Cobbett does not deny that a relative immunity can be produced to the tubercle bacillus by inoculation with a suitable antigen, which I have shown is all that is necessary, and since he acknowledges isolation will not succeed in cutting off the source of infection, I must refuse to allow this measure of preventive inoculation to be side-tracked.—I am, Sir, yours faithfully,

W. M. CROFTON, M.D.

University College, Dublin, Dec. 17th, 1917.

THE LATE DR. ELSIE INGLIS.

To the Editor of THE LANCET.

SIR,—In the delightful and appreciative account of Elsie Inglis in your issue of Dec. 8th it is stated that she was brought up in "the strict tenets of the Plymouth Brotherhood." The facts are so much the opposite that it is perhaps worth while stating them. Her family on both sides have always belonged to the Anglican Church, and the atmosphere in which she was brought up was one of the most generous tolerance and of the widest and sanest outlook. Her family history in the religious line explains largely her own wide, sympathetic view of men and nations. She herself was a member of the Church of Scotland.

I am, Sir, yours faithfully,

Dec. 21st, 1917. E. H. MCL.

Obituary.

WILLIAM GILMORE ELLIS, M.D., M.R.C.S.,

PRINCIPAL CIVIL MEDICAL OFFICER, STRAITS SETTLEMENTS.

Dr. Gilmore Ellis, who died after an operation at the General Hospital, Singapore, on Oct. 8th last at the age of 57 years, obtained his medical education at St. Bartholomew's Hospital, London, qualifying in 1882, and taking his M.D. Brussels five years later. After acting for a time as resident medical officer and science master at Wellington College he became surgeon to the Eastern Extension Telegraph Company before settling down to his life's work in mental diseases. His first lunacy appointment was at Banstead, and in 1888 he was selected by the Secretary of State as medical superintendent of the Singapore Asylum, a post which he held for nearly 22 years, until his appointment in 1910 as principal civil medical officer of the Straits Settlements. A seat in the Legislative Council followed shortly after.

Dr. Ellis's long colonial career was one of ceaseless activity. At various times he acted as health officer to the Singapore Municipality and as resident surgeon to the General Hospital. He was one of the original members of the Straits Medical Association, founded in April, 1890, and during the life of that body was a constant contributor of clinical notes and papers. To the *Journal of Mental Science* he also contributed many articles of psychological value. During the eight years through which he filled the highest medical post in the colony he showed himself a good administrator as well as an indefatigable worker. Although due to retire on pension, at the outbreak of the war he offered to continue in harness in order to tide over the strain occasioned by the absence of nearly half the medical staff. This effort was doubtless contributory to his sudden illness and death; and it was no empty form which accorded him a funeral with full military honours.

Dr. Ellis's widow and two daughters survive him, as well as two sons who hold commissions in the Army and are on active service.

THE SERVICES.

ARMY MEDICAL SERVICE.

Lieutenant-Colonels relinquishing the rank of temporary Colonel on re-posting: A. W. Hooper, C.M.G., D.S.O.; M. MacG. Rattray, D.S.O.

Lieut.-Col. F. J. Greig, C.M.G., Reserve of Officers, relinquishes the rank of temporary Colonel on re-posting.

Lieutenant-Colonels to be temporary Colonels whilst employed as Assistant Directors of Medical Services of Divisions: E. W. W. Cochrane, L. N. Lloyd, C.M.G., D.S.O., J. H. Campbell, D.S.O.

Temporary Colonels to be temporary Surgeon-Generals: Sir W. P. Herringham, C.B., Sir J. R. Bradford, K.C.M.G., C.B., Sir B. E. Dawson, K.C.V.O., C.B., C. S. Wallace, C.M.G., Sir B. G. A. Moynihan, C.B.

ROYAL ARMY MEDICAL CORPS.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Major (temporary Lieut.-Col.) T. J. Wright, D.S.O., Capt. (temporary Lieut.-Col.) A. Irvine-Fortescue.

Major B. S. Bartlett retains the acting rank of Lieutenant-Colonel whilst commanding a Casualty Clearing Station.

Capt. H. A. T. Fairbank, R.A.M.C., T.F., to be temporary Lieutenant-Colonel.

Majors to be acting Lieutenant-Colonels whilst in command of a Medical Unit: P. C. T. Davy, C.M.G., R. H. Bridges, D.S.O.

Major E. T. Potts, D.S.O., to be acting Lieutenant-Colonel whilst employed as Assistant Director of Medical Services of an Army.

Major J. H. Graham is placed temporarily on the Half-pay List on account of ill-health.

R. F. Kennedy to be temporary honorary Major whilst serving with a General Hospital.

J. W. B. Thorburn, late temporary Captain, is granted the honorary rank of Captain.

Temp. Capt. J. M. Macmillan to be temporary Major.

Temporary Lieutenants to be temporary Captains: R. Cope, J. G. Macqueen, J. C. L. Day, A. Leeming, G. Cooper, C. Murphy, W. E. Burrows, E. W. Milne, S. E. Holder, T. F. Murphy, R. C. Corbett, A. MacMillan, A. B. Coomber, S. P. Pollard, C. E. Clay.

To be temporary Honorary Lieutenants: C. R. Bird, G. Lucas, D. E. Carter, A. Gregg, E. B. Fitzgerald, J. E. Bloomer, H. W. Woodward, W. M. Findley.

Officers relinquishing their commissions: Temp. Capts. W. B. Seaton, G. McI. Dale, G. A. McLarty, J. R. Burn, A. E. McKibbin, G. M. Huggins, J. B. Yelf, A. L. H. Rackham; Temp. Lieut. L. G. Teece (on account of ill-health), H. S. Vivian.

Canadian Army Medical Corps.

Temp. Lieut.-Col. J. M. Elder to be temporary Colonel.

Temp. Major A. C. Rankin to be temporary Lieutenant-Colonel.

Temp. Capt. (acting Lieut.-Col.) A. Croll to be temporary Major and to retain the acting rank of Lieutenant-Colonel.

Temporary Captains (acting Majors) to be temporary Majors: J. J. Ower, R. J. McEwen, T. F. O'Hagan, M.C., R. H. Smith, S. G. Ross, M.C., R. H. M. Hardisty, H. Buck, G. W. Treleaven, H. E. Paul.

Temporary Captains to be temporary Majors: R. F. Flegg, J. L. Cock, G. O. Taylor, R. M. Luton, M.C., J. McW. Taylor, A. H. Taylor, M.C., W. Brown, M.C., D. McLellan, J. W. Pilcher, N. G. Cooper, T. L. Butters, G. C. Hale, H. P. Wright, F. S. Ruttan, J. M. Stewart, H. H. Burnham, H. B. Boyd, E. D. Hubbell, J. H. M. Bell.

Temp. Capt. C. W. Waldron to be acting Major while specially employed.

To be temporary Captains: W. E. Ainley, Temp. Lieut. A. B. Whytock, Temp. Lieut. E. C. A. Crawford.

Canadian Army Dental Corps.

Temporary Lieutenants to be temporary Captains: E. G. Berry, R. H. Aljoe, C. N. Westwood, J. H. Reid, A. G. Fraser (from Western Ontario Regiment).

SPECIAL RESERVE OF OFFICERS.

Temp. Capt. D. McIntyre, from R.A.M.C., to be Captain.

TERRITORIAL FORCE.

Capt. (Brevet Major) R. L. Guthrie to be acting Lieutenant-Colonel whilst in command of a Hospital.

Temp. Capts. G. Hollies and J. Lytle to be temporary Majors, Shropshire Medical Volunteer Corps.

R. M. Wilson (late Lieutenant Colonel, R.A.M.C., T.F.), to be Medical Officer and temporary Captain, 1/1st Batt. County of Aberdeen Volunteer Regiment.

Capt. D. McP. Taylor relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

Lieut.-Col. (Brevet-Col.) H. W. Webber is restored to the establishment.

Capt. (acting Lieut.-Col.) C. Cameron relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. H. L. P. Hulbert relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

G. T. Giddings to be temporary Major, and R. M. H. Randall and A. C. Haslam to be temporary Captains, Kent Medical Volunteer Corps.

C. W. Pilcher to be temporary Captain, Lincolnshire Medical Volunteer Corps.

TERRITORIAL FORCE RESERVE.

Capt. C. T. Matthews, from Field Ambulance, to be Captain.

URBAN VITAL STATISTICS.

(Week ended Dec. 15th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was equal to 13·6, against 11·9 and 12·4 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 13·7, or 0·6 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 5·2 in Rochdale, 5·5 in Edmonton and in Great Yarmouth, and 7·2 in Huddersfield, to 21·4 in Liverpool, 21·9 in Stockton-on-Tees, and 22·4 in South Shields. The principal epidemic diseases caused 376 deaths, which corresponded to an annual rate of 1·2 per 1000, and included 119 from measles, 110 from whooping-cough, 67 from diphtheria, 56 from infantile diarrhœa, 17 from scarlet fever, and 7 from enteric fever. Measles caused a death-rate of 2·7 in Acton, 3·5 in St. Helens, 4·1 in Leicester, and 4·5 in Brighton, and whooping-cough of 1·6 in Liverpool, 1·9 in Wigan, and 2·3 in Middlesbrough. The 1330 cases of scarlet fever and 1679 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 21 below and 44 above the numbers remaining at the end of the previous week. Of the deaths from all causes in the 96 towns, 150 resulted from violence. The causes of 50 deaths were uncertified, of which 6 were

registered in Liverpool, 4 each in Birmingham and Manchester and 3 each in Preston, Barrow-in-Furness, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 13·1, against 12·5 and 12·9 per 1000 in the two preceding weeks. The 269 deaths in Glasgow corresponded to an annual rate of 12·6 per 1000, and included 7 from infantile diarrhœa, 6 from diphtheria, 5 from whooping-cough, 2 from enteric fever, and 1 from measles. The 76 deaths in Edinburgh were equal to a death-rate of 11·9 per 1000, and included 3 each from measles and diphtheria and 1 from scarlet fever.

Irish Towns.—The 135 deaths in Dublin corresponded to an annual rate of 17·6, or 0·8 per 1000 below that recorded in the previous week, and included 2 each from measles, whooping-cough, and diphtheria, and 1 each from enteric fever and infantile diarrhœa. The 93 deaths in Belfast were equal to a rate of 12·3 per 1000, and included 4 from infantile diarrhœa and 2 each from measles and whooping-cough.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1917.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,237,387 persons; in the three preceding months the rates had been 3·1, 4·2, and 5·3 per 1000. The lowest rates in November were recorded in Paddington, Kensington, St. Marylebone, Stoke Newington, Holborn, and the City of London; and the highest rates in Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, Wandsworth, and Greenwich. The prevalence of scarlet fever showed a marked increase over that recorded in other recent months; this disease was proportionally most prevalent in Fulham, Chelsea, Bethnal Green, Bermondsey, and Wandsworth. The Metropolitan Asylums Hospitals contained 1335 scarlet fever patients at the end of the month, against 615, 807, and 1180 at the end of the three preceding months; the weekly admissions averaged 191, against 83, 138, and 177 in the three preceding months. Diphtheria was more prevalent than it had been in any of the preceding months of this year; the greatest proportional prevalence of this disease was recorded in Shoreditch, Bethnal Green, Southwark, Bermondsey, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1003, 1111, and 1393 at the end of the three preceding months, had risen to 1656 at the end of November; the weekly admissions averaged 239, against 122, 163, and 206 in the three preceding months. The prevalence of enteric fever was slightly more than in the preceding month; of the 34 cases notified in November, 7 belonged to Wandsworth, 5 to Stepney, 4 to Bethnal Green, 3 to St. Pancras, and 3 to Islington. There were 36 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 45, 46, and 38 at the end of the three preceding months; the weekly admissions averaged against 6, 6, and 3 in the three preceding months. Erysipelas was proportionally most prevalent in Islington, Shoreditch, Stepney, Poplar, Southwark, Lambeth, and Deptford. The 18 cases of puerperal fever notified during the month included 2 each in Fulham, Islington, Hackney, Poplar, Southwark, Lambeth, and Woolwich. Of the 13 cases of cerebro-spinal meningitis 4 belonged to Bethnal Green, 2 to Lambeth, 2 to Islington, 2 to Finsbury, 2 to Stepney, 2 to Poplar and 2 to Wandsworth; while of the 4 cases of poliomyelitis 2 belonged to Fulham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Dec. 1st the deaths of 4068 London residents were registered, equal to an annual rate of 12·6 per 1000; in the three preceding months, the rates had been 10·5, 11·0, and 12·5 per 1000. The death-rates in November ranged from 8·5 in Hampstead, 8·9 in Lewisham, 9·1 in the City of London, 9·2 in Fulham, and 10·3 in Woolwich, to 13·7 in Islington, 14·3 in Holborn, 14·9 in Southwark, 16·5 in Bermondsey, 24·1 in Finsbury, and 25·2 in Shoreditch. The 4068 deaths from all causes included 346 which were referred to the principal infectious diseases; of these, 155 resulted from measles, 9 from scarlet fever, 53 from diphtheria, 44 from whooping-cough, 5 from enteric fever, and 80 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded during the month in Chelsea, Stoke Newington, and the City of London; among the metropolitan boroughs they caused the lowest death-rates in Hammersmith, the City of Westminster, St. Marylebone, Hampstead, Wandsworth, Greenwich, and Lewisham; and the highest death-rates in Holborn, Finsbury, Shoreditch, and Stepney. The 155 deaths from measles were 50 above the corrected average number in the corresponding period of the five preceding years, and included 66 in Shoreditch, 37 in Finsbury, 19 in Stepney, and 7 in Islington. The 9 deaths from scarlet fever were 14 below the corrected average number, and included 4 in Wandsworth, 2 in Hackney, and 1 in Stepney. The 53 fatal cases of diphtheria about equalled the corrected average number; the greatest proportional mortality from this disease occurred in Shoreditch, Bethnal Green, Southwark, Bermondsey, and Lambeth. The 44 deaths from whooping-cough were 9 in excess of the corrected average number; this disease was proportionally most fatal in Shoreditch, Poplar Bermondsey, and Battersea. The 5 deaths from enteric fever were 3 below the corrected average, and included 1 each in Fulham, the City of Westminster, Islington, Stepney, and Southwark. The 80 deaths from diarrhœa and enteritis among children under 2 years of age were less than three-fifths of the corrected average number; the greatest proportional mortality from this cause was recorded in Paddington, St. Pancras, Holborn, Shoreditch, Lambeth, and Battersea. In conclusion, it may be stated that the aggregate mortality in London in November from these principal infectious diseases was 5 per cent. below the average.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING NOVEMBER, 1917.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1916.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. J. McD. Matheson, R.A.M.C., attached Middlesex Regiment, qualified at Glasgow in 1916, and joined up shortly afterwards.

Died of Wounds.

Capt. N. McG. Smith, R.A.M.C., qualified at Glasgow in 1915, and thereupon joined the R.A.M.C.
Major T. J. Frizelle, Australian A.M.C.

Wounded.

Capt. J. F. W. Meenan, R.A.M.C.
Lieut. E. E. Owens, R.A.M.C., attached S. Staffs. Regiment.
Capt. A. E. Delgado, R.A.M.C., attached R.F.A.
Capt. D. T. Evans, R.A.M.C., attached Scottish Rifles.
Lieut. H. J. Henderson, R.A.M.C., attached Essex Regiment.
Major P. A. Maplestone, Australian A.M.C.
Capt. J. Manuel, R.A.M.C., attached Worcester Regiment.
Capt. O. Matthews, Australian A.M.C.
Capt. P. J. O'Shea, Australian A.M.C.
Capt. T. A. Townsend, R.A.M.C., attached London Regiment.
Capt. C. Cheochi, Australian A.M.C.
Capt. E. H. Lawson, R.A.M.C., attached N. Staffs. Regt.
Capt. R. G. Burnard, Australian A.M.C.
Capt. J. R. Forde, R.A.M.C., attached Leicester Regiment.
Capt. J. E. S. Smith, R.A.M.C.

Previously reported Wounded, now reported not Wounded.

Mathews, Capt. O., Australian A.M.C.

Missing.

Capt. F. W. Fawssett. R.A.M.C., attached L.N. Lancs. Regt.
Capt. H. B. Goulding, R.A.M.C., attached Gloucester Regt.
Capt. J. Davidson, R.A.M.C., attached K.R.R.C.
Capt. H. H. Fairfax, R.A.M.C., attached R. Warwick Regt.
Lieut. A. S. Garewal, I.M.S.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieut. A. M. Alexander, London Regt., killed in action, second son of Dr. S. P. Alexander, of Southsea.
Capt. G. F. Griffith, London Regt., previously reported missing, believed killed, now presumed killed in action, younger son of Dr. W. S. A. Griffith, of Harley-street, London, W.
Second Lieut. G. H. W. Gough, Cheshire Regt., killed in action, eldest son of Mr. H. E. Gough, M.R.C.S., medical officer of health of Northwich, Cheshire.
Second-Lieut. H. C. Elliott, Royal Engineers, died of wounds, second son of Dr. C. Elliott, of Clifton, Bristol.

FOREIGN DECORATIONS.

French.

Légion d'Honneur.—Croix de Commandeur: Surg.-Gen. H. R. Whitehead, K.C.B., R.A.M.C. *Croix d'Officier:* Lt.-Col. F. J. Brakenridge, C.M.G., R.A.M.C.; Lt.-Col. H. J. M. Buist, D.S.O., R.A.M.C.; Col. S. F. Clark, R.A.M.C. *Croix de Chevalier:* Capt. W. L. Murphy, R.A.M.C.

Croix de Guerre.—Temp. Lieut. W. E. Ord, R.A.M.C.; Capt. (acting Lt.-Col.) A. D. Fraser, D.S.O., M.C., R.A.M.C.

THE SHORTAGE OF MEDICAL MEN: THE ACTION OF THE MINISTRY OF NATIONAL SERVICE.

The Medical Examination of All Practitioners of Military Age.

To enable the Minister of National Service to compile an index brought up to date of the physical fitness of all medical practitioners throughout the country who are of military age, irrespective of whether they have or have not already served in the Royal Army Medical Corps, notices have been sent to such doctors requesting them, notwithstanding any previous examination, to present themselves for medical examination by a National Service Medical Board on or before Jan. 12th, 1918. If the doctor's ordinary residence is more than five miles distant from the place of examination his railway fare will be paid by the Ministry of National Service on application to the Deputy Commissioner of Medical Services. There is not the slightest need for any man who receives this notice to be under any misapprehension about it. In no sense is it a calling up notice; nor is it even a preliminary to a calling up notice, except in the case of men who would in any circumstances come under the consideration of the Professional Committees for Military Service.

The Annual Contract Call to Doctors who have Resigned Commissions since Oct. 31st.

It has been decined, with a view to maintaining the required number of officers in the Royal Army Medical Corps consistently with the least disorganisation of medical service throughout the country, to call upon all medical practitioners of military age who have resigned, or may resign, their temporary commissions on the expiry of an annual contract on and after Oct. 31st, 1917, to resume their commissions. This decision has not been arrived at without a very full consideration of the medical needs of the civilian population on the one hand and of the urgent requirements of the Army on the other, as well as of the services which such officers have already rendered. This proposal will not affect the customary privilege which has hitherto been accorded to the profession of laying any difficulties which individual practitioners may have in accepting or resuming service before a Committee of their professional colleagues.

The Minister of National Service, therefore, urgently requests the doctors concerned immediately to place themselves in the hands of the appropriate Central Committee in order that this Committee may be put in possession of the facts which will enable it to determine whether their services may again be placed at the disposal of His Majesty's Government.

The following are the addresses of the Central Professional Committees:—

The Central Medical War Committee, 429, Strand, London, W.C. 2, for all enrolled practitioners in England and Wales.

The Committee of Reference, 8 to 11, Queen-square, London, W.C. 1, for practitioners on the staffs of all hospitals in the London area.

The Scottish Medical Service Emergency Committee, 9, Queen-street, Edinburgh, for practitioners in Scotland.

VILLAGE CENTRES FOR THE CURE AND TRAINING OF EX-SERVICE MEN.

At the House of Commons meeting on Dec. 10th (see THE LANCET, Dec. 15th, p. 915) the question was raised as to the attitude of the Ministry of Pensions towards the scheme of the Village Centres Committee. As the result of a deputation which waited upon Sir Matthew Nathan on Dec. 14th the Ministry of Pensions has now signified its definite approval, so far as the general scheme of treatment and training of disabled men is concerned. While not otherwise associating itself with the part of the scheme relating to village settlement, the Ministry raises no objection to some of the temporary residents at a centre becoming permanently resident in the village if they desire to do so. The capitation grants will go far to cover the running expenses of the centre, and a grant for equipment of the workshops is being considered by the Minister of Pensions. The scheme for a metropolitan village centre for the London district is therefore now being made public. An estate has been chosen suitable for the purposes in view, and favourable reports upon the site and buildings have been received from medical, agricultural, horticultural, and industrial experts who have viewed the place. A Mansion House meeting will shortly be held to issue an appeal for funds to purchase the property. It is estimated that a sum of £150,000 may be required for the complete scheme.

METROPOLITAN HOSPITAL SUNDAY FUND.—The Lord Mayor of London presided over the annual meeting of the constituents of this Fund at the Mansion House on Dec. 20th, when the report of the Council for 1917 was unanimously adopted on the motion of Sir C. Ernest Tritton. The report stated that £76,354 6*s.* 5*d.* had been collected during the year, an increase of £5654 upon last year's figures. The collections in the various places of worship had resulted in a sum of £37,339, or £2218 more than in 1916. Sir Ernest Tritton said that never had the hospitals rendered such services to the community as they had in the past year. Their ministration to sailors, soldiers, airmen, women and children who had been victims of the air raids, and to the sick poor made everyone their debtors. The retiring members of the Council were re-elected for the forthcoming year and the following names were added: the Rev. Preb. Grose Hodge, Rev. Austin Thompson, Mr. John Latta, Mr. J. E. Moxey, Dr. W. T. Partridge, and Mr. Robert McConnell. Hospital Sunday for 1918 was fixed for June 23rd.

THE LANCET, VOL. II., 1917: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 29th will be ready early in the New Year. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR MEDICAL DEGREES.

Part I.—Ormonde Alan Baker, University College; Joyce Rayner Batten, Newnham College; Dorothy Josephine Collier, London School of Medicine for Women; David Justin Davies, University College, Cardiff; Betty Dent, London School of Medicine for Women; Kenneth Henry Doouss, St. Bartholomew's Hospital; Keridwen Valentine Edwards, University College, Cardiff; Geoffrey Edward Woollcombe Felce, Guy's Hospital; Elizabeth Mai Genge, London School of Medicine for Women; Egerton Charles Grey, Guy's Hospital; Fred Cecil Hunt, London Hospital; Thomas Evans Jones, University College; Barney Kessel, Guy's Hospital; David Krestin, London Hospital; Alfred Quentin Logan, St. Thomas's Hospital; Mary Catherine Lynch and Dorothy McNair, London School of Medicine for Women; Framroz Nanabhoy Moos, Grant Medical College, Bombay, and Middlesex Hospital; Gwendolen Mary Pratt, London School of Medicine for Women; William Hedley Summerskill, Guy's Hospital; Maurice Lister Sutcliffe University College; Dick Brasnett Sutton, King's College; Harold Keith Tucker, St. Bartholomew's Hospital; Enid Margaret Williams, King's College; and Charles Paul Wilson, Middlesex Hospital.

Part II.—Percy Croad Brett, St. Mary's Hospital; Francis Cavers, University College; George William Cheater, King's College; John Joseph Coghlan, London Hospital; *†Rustam Nusserwanji Cooper, Middlesex Hospital; Charles Owen Davies, University of Liverpool; Evan Sherrah Davies, King's College and Westminster Hospital; James O'Farrell Fletcher, St. Mary's Hospital; Edward Emile Delisle Gray and Egerton Charles Grey, Guy's Hospital; Donald Hunter and Charles Arundel Hutchinson, London Hospital; Margaret Hypatia Kingsford, London School of Medicine for Women; ‡Geraldine Zarita Lee Le Bas, University, King's, and Bedford Colleges; Joseph Proujansky, London Hospital; James Victor Alexander Simpson, Middlesex Hospital; Madeline Hilda Jane Umpleby, London School of Medicine for Women and King's College; and Jacob Elias Zeitlin, London Hospital.

* Distinguished in Anatomy. † Distinguished in Physiology. ‡ Distinguished in Pharmacology.

M.D. EXAMINATION.

Branch I., Medicine.—Dorothy Cnick, B.S., London School of Medicine for Women; Hugh James Orr Ewing, B.S. (University medal), University of Bristol; Mary Emmeline Joll, B.S., London School of Medicine for Women; and George William Lloyd, B.S., St. Bartholomew's Hospital.

Branch V., State Medicine.—Philip Smith, B.S., King's College and Guy's Hospitals.

M.S. EXAMINATION.

Branch I., Surgery.—William Edward Tanner, Guy's Hospital.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

FINAL M.B. AND CH.B.

C. F. J. Carruthers, James Charnley, J. C. T. Fiddes, M. C. Paterson, R. S. Paterson, and Elizabeth C. Powell.

Forensic Medicine.—Thomas Colley, S. E. Critchley, and F. L. Whincup.

THIRD M.B. AND CH.B. EXAMINATION.

General Pathology and Morbid Anatomy.—Nooman Abdoh, Elizabeth C. Davies, Kathleen Doyle, Georgiana M. Duthie, Olive M. Gimson, F. G. Hamnett, Archibald Harris, Simon Kelly, J. N. Laing, J. G. Nolan, Olga G. M. Payne, F. L. Pickett, Effie Ratner, William Reikan, Annie G. Thompson, Doris M. R. Tompkin, and Ruth A. Wilson.

Pharmacology and Therapeutics.—R. J. Allison, Mary E. Boullen, Percival Fildes, Archibald Harris, A. E. H. Sadek, Ethel D. Willis, and James Yates.

Hygiene.—R. J. Allison, A. M. Cotes, E. B. A. Edelston, A. E. H. Sadek, Ethel D. Willis, and James Yates.

SECOND M.B. EXAMINATION.

May Ashburner, Martha F. Barritt, May Blakiston, F. A. van Coller, Phyllis M. Congdon, Margaret MacF. Corbold, J. W. Crawshaw, K. V. Deakin, Dorothy M. L. Dyson, A. M. El Aguizy, F. R. Ferguson, Evelyn A. Garnett, Joshua Harris, Sylvia K. Hickson, Irma Jehansart, Violet M. Jewson, Mary S. Jones, *H. A. Lomax, Alexander Maude, Doris B. Norman, *Emily M. Peach, Harry Rosenthal, *†Gerald Sheehan, Florence G. Sherry, Constance Snowdon, Annie E. Somerford, Geoffrey Talbot, Doris A. Taylor, H. W. Taylor, Mary I. Turner, Raymond Williamson, J. E. Wright.

* Distinction in Anatomy. † Distinction in Physiology.

Anatomy.—Florence M. L. Graham.

FIRST M.B. EXAMINATION.

Part III. (Organic and Bio-Chemistry).—Catherine M. E. S. Chapman, Gwendolen A. G. Edwardes-Evans, James Leather, Gertrude B. Leigh, and Nellie P. Marshall.

DIPLOMA IN DENTISTRY (*Final Examination*).

Dental Surgery, Dental Prosthetics, and Operative Dentistry.—Norman Flitcroft.

Third Examination.—E. L. Morgan.

UNIVERSITY OF BRISTOL.—At the Second Examination for the conjoined degrees of M.B., Ch.B. (Part I.), held recently, the following candidates were successful:—

Phyllis Beames, Macdonald Critchley, Madge Edith Golding, Winifred Grace Nott, John Augustin Prichard, Hilda Elizabeth Reynolds, Phyllis Thekla Siepmann, and Victoria Sophia Tryon.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Dec. 18th the following gentlemen, having passed the requisite examinations between Oct. 1st and 3rd, were admitted Fellows:—

Arthur Frederick Cole, Subodhchandra Datta, Sidney Forsitte, Joseph Geoghegan, William Moir Webster Shepherd, Robert Tennent, and Nathan Judah Wigram.

At the same meeting Mr. David Percival Dalbreck Wilkie was awarded the Liston Victoria Jubilee Prize of £100 for his valuable work and contributions with reference to abdominal surgery.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred recently:—

M.B. and Ch.B.—John Bernard Mutch, Dennis Joseph Viegas Pereira, and Henry Roger.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Dec. 13th, with Sir Francis H. Champneys in the chair. A letter was considered from Dr. W. E. Fothergill, one of the Board's examiners from the Liverpool and Manchester Centre, forwarding certain criticisms by the examiners of that centre on some questions set at recent examinations. The Board decided that Dr. Fothergill be informed that the Board thinks that it is impossible to eliminate technical terms in teaching midwives: if they did so, the result would be to dissociate midwives from all relation with books referring to the study and practice of midwifery, and persons engaged therein. As regards elementary physiology, it rests with the teachers to make the subject intelligible to their pupils. It must be remembered that only such physiology is required as will make the subject of midwifery in its turn intelligible. To omit all instruction in elementary physiology would be to throw pupil midwives back upon their own resources; and it is with the view of rendering physical processes concerned in midwifery intelligible that elementary physiology was introduced into the syllabus. The Board recognises that the mental and educational standard of pupils varies in different localities, and believes that the teachers in Manchester have more difficulty from this cause than in many other centres. It has, however, taken the representations of Dr. Fothergill into consideration, and communicated them to the examiners in question.—Correspondence with the county medical officer of health for Derbyshire with regard to the practice adopted in that county in respect of the suspension of midwives was considered. The Board decided that Dr. S. Barwise be thanked for his letter. The Board hopes that an understanding will be arrived at between the local authority and the midwives as to the mode of disinfection authorised, and that the inspector may be sent, if necessary, as soon as the infection becomes known to the authority.—Correspondence with a Dutch subject, praying for admission to the Board's examination, was considered. The Board decided that, having satisfied the Board of her Dutch nationality, she be admitted to examination subject to compliance with the regulations prescribed for examination candidates.—Correspondence with a candidate of German origin, but the widow of an Englishman, and now domiciled in the United Kingdom, praying for admission to the examination, was considered. The Board decided that she be not admitted to examination during the period of the war.

INSTITUTE OF MASSAGE AND REMEDIAL GYMNASTICS.—The second annual general meeting of the Institute of Massage and Remedial Gymnastics was held in the Council Chamber of the University of Manchester on Friday, Dec. 7th. Sir W. Cobbett, President of the Institute, in the chair. Sir W. Milligan, chairman of the Executive Council, having given a report of the year's working, alluded to negotiations which took place between the Institute and the Incorporated Society of Trained Masseuses. It was unanimously agreed to authorise the executive to proceed with negotiations with a view to amalgamation with the Incorporated Society

Trained Masseuses, the final amendments and suggestions for union being as follows:—

(*a*) Registration on passing prescribed examinations to carry membership, and membership to carry the right to propose and elect representatives on the council. Men as well as women to be admitted to membership, and masseurs to have direct representation on the council in proportion to their numbers, with a minimum of one representative.

(*b*) All applications for membership from present holders of the society's certificate (1917) to be considered individually by the council up to a date to be determined later. Trained masseuses and masseurs holding a certificate other than that of the society may also become members after such tests as the council may determine.

(*c*) In addition to the founders and the representative of the masseurs, the council to consist as to two-thirds of elected and one-third of co-opted members. Two-thirds at least of the co-opted members to be medical men and women experienced or interested in massage or medical electricity, while one-third may be persons holding a certificate of massage, but if these are co-opted they must be members of the society.

(*d*) Of the elected members of the council, half to be proposed and elected as representatives of the recognised schools in which they shall be teachers or officials, and the remaining half to be other than teachers or officials in recognised schools.

(*e*) The names of all duly nominated candidates for council to be circularised to all persons on the society's register before the annual general meeting, and the election to be by postal ballot.

(*f*) Retirement from the council to be by rotation, one-third of the council going out every year, but retiring members to be eligible for re-election. The council to have power to elect a president and three vice-presidents to be *ex-officio* members of the council for a period of five years, when on retirement, they shall be eligible for re-election.

(*g, h, and i*) Examiners in practical subjects to be interchanged between various parts of the country; papers to be set by an examining board for the United Kingdom. Local boards to be appointed by the council as to two-thirds from persons nominated by the recognised training schools in the area, one-third being teachers or officials and one-third medical men and women interested in massage or medical electricity, and as to one-third by those persons on the register of the society resident in the area.

The financial control of the amalgamated bodies will rest with the council.

HUNTERIAN SOCIETY.—A meeting of this society will be held on Wednesday, Jan. 2nd, 1918, at 5 P.M., at the Royal Society of Medicine, 1, Wimpole-street, London, W., when the second Hunterian lecture will be delivered by Sir Robert Jones, C.B., F.R.C.S., on "War-time Orthopædic Surgery."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliamentary Recess.

PARLIAMENT adjourned over Christmas. The House of Lords reassembles very early in the New Year, but the House of Commons will not meet until Monday, Jan. 14th.

The Midwives (Ireland) Bill.

The Midwives (Ireland) Bill still awaits second reading. Motions in opposition to it stand on the notice paper in the names of Mr. SCANLAN, Mr. CRUMLEY, and Mr. O'SHEE.

HOUSE OF COMMONS.

TUESDAY, DEC. 18TH.

Grants in Aid of Auxiliary Hospitals.

Sir WILLIAM COLLINS asked the Financial Secretary to the War Office from what date the increased grants in aid of auxiliary hospitals, Classes A and B, of 3*s.* 3*d.* and 2*s.* 6*d.* respectively, had been payable; when the increased grants recently announced would be made payable in the case of voluntary hospitals established before the war and which were now receiving wounded soldiers as in-patients; and what the maximum grants to such hospitals in respect of such service would be.—Mr. FORSTER replied: The new rates which are maxima take effect from August 1st, 1917. If the hospitals referred to in the second part of the question are established civil hospitals, they are in receipt of grants on a different scale, and the question of increasing those grants is under consideration.

WEDNESDAY, DEC. 19TH.

Small-pox Cases in the Army.

Replying to Mr. BENTHAM, Mr. MACPHERSON wrote: The number of cases of small-pox in the Army in 1916 was 10; of these, 6 were unvaccinated, 5 of them recovered, and 1 died. Three were vaccinated in infancy, of whom 2 recovered and 1 died. One who was revaccinated, recovered.

Convalescent Soldiers.

Mr. BOWERMAN asked the Under Secretary for War whether wounded sailors and soldiers in hospital in this country were, when convalescent, allowed to go to their homes for a few days and then return to hospital or convalescent home or to their unit, and might then remain in this country for several weeks before returning to France or to their ships without being granted a second period of leave; and whether he would consider the desirability of allowing such men further leave for home-visiting purposes.—Mr. MACPHERSON replied: Unless for very urgent reasons, no soldier patient in hospital receives any leave. On discharge from hospitals all returned Expeditionary Force soldiers receive a furlough of 10 days before joining either a reserve unit or a command depôt. A soldier on home service admitted to hospital may, if the medical officer considers it necessary, also receive up to 10 days leave. If a soldier returned from an Expeditionary Force remains in this country for six months after his hospital furlough he again receives leave for a few days to his home. If a home-service soldier, he receives the same leave after nine months. All soldiers, if the exigencies of the service permit, receive four days' home-leave before being drafted overseas. With regard to sailors I must refer my honourable friend to the Secretary to the Admiralty.

Sale of Sterilised Meat.

Mr. W. THORNE asked the Parliamentary Secretary to the Ministry of Food whether a sterilised meat shop had been opened in Aberdeen, and, if so, was he in a position to issue a report about the matter.—Mr. CLYNES answered: I am informed that such a shop was opened last Saturday. I am obviously not in a position to issue a report about the matter.

Disabled and Discharged Soldiers.

Mr. DUNCAN MILLAR asked the Parliamentary Secretary to the Ministry of Pensions how many institutions had now been provided in Scotland for the treatment of disabled soldiers and sailors; and how many soldiers and sailors were receiving treatment in that country.—Sir A. GRIFFITH-BOSCAWEN answered: The number of institutions available for the treatment of disabled men in Scotland is 230, and further institutions are being provided. The total number of discharged men under treatment is not reported, but the number under treatment who are in receipt of a full allowance in lieu of pension under Article 6 of the Royal Warrant is 638.

Mr. HOGGE asked whether there were any training centres for discharged men in Ireland.—Sir A. GRIFFITH-BOSCAWEN answered: In Dublin training is in operation in optical and astronomical instrument-making, basket-making, carpentry, toy-making, gardening, care and management of horses, clerical work, manufacture, &c., of artificial limbs, pipe-making, and as motor mechanics. In Belfast there is training in commercial subjects, and courses have been sanctioned, but are not yet in operation, for cane chair-seat making, French polishing, and domestic assistance in hotels. Schemes for instruction in boot-repairing and box-making are under consideration.

THURSDAY, DEC. 20TH.

Army Dental Service.

Mr. PENNEFATHER asked the Under Secretary for War whether he had received an advance copy of a report about to be issued by a Parliamentary Committee which had been considering the relation between man-power and the Army dental service; and, if so, would he state what, if any, steps would be taken to carry out the recommendations contained in the report.—Mr. MACPHERSON said in reply: I received the advance copy of the report which my honourable friend has sent me. There has not been time to examine it, and I shall be obliged if my honourable friend will put his question down again in January.

Soldiers Suffering from Shell Shock.

Mr. HUGH LAW asked the Under Secretary for War whether he could assure the House that before soldiers who had been invalided suffering from shell shock or other nervous trouble were sent back to the front they were examined by a medical board containing at least one specialist in nervous diseases.—Mr. MACPHERSON answered: I cannot give this assurance at present, but under the new arrangements it is hoped that this desirable end will be attained.

Small-pox Case in the Navy.

Answering Mr. BENTHAM, who asked how many sailors developed small-pox in the year 1916, Mr. MACNAMARA (Secretary to the Admiralty) wrote: One such case occurred during 1916. The man recovered. No particulars are available regarding vaccination or revaccination in the case in question, but as the man was a stoker, Royal Naval Reserve, he was liable to be vaccinated or revaccinated as a condition of his entry into the Royal Naval Reserve.

Public Vaccinator for Dewsbury.

Mr. CHANCELLOR asked the Parliamentary Secretary to the Local Government Board whether the public vaccinator for Dewsbury was still paid by salary, and how many vaccinations he had performed during the past three years.—Mr. STEPHEN WALSH answered: The reply to the first part of the question is in the affirmative. The number of successful primary vaccinations performed by this public vaccinator at the cost of the rates during the years ended

Sept. 30th, 1914, 1915, and 1916, respectively, is 1021, 909, and 821.

The Cocaine Committee.

Mr. PEMBERTON BILLING asked the Home Secretary whether he had received a report as to the progress and recommendations, if any, of the Cocaine Committee; how many sittings this committee had held within the last six months; whether any changes had been made in the personnel of this committee during this period; what was the annual cost to the State of this committee, including salaries, rent, rates, taxes, printing, posting, and stationery; and whether this committee was to be continued.—Sir GEORGE CAVE replied: The Cocaine Committee was appointed by the Secretary of State at the time when the Defence of the Realm Regulation 40B, which regulates dealings in cocaine and opium, was made, for the purpose of advising upon any applications for permits under the regulation that might be made to them. A considerable number of applications were referred to, and reported upon by, the committee. It has not been necessary for the committee to hold any sittings during the last six months, but it is proposed to continue it in existence to deal with cases which may arise from time to time. There has been no change in its personnel. Accommodation and secretarial assistance have been provided at the Home Office, and no special expenditure in respect of salaries, rent, printing, &c., has been incurred.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).
When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

AUSTRALIA, COMMONWEALTH OF.—One Biochemist, salary £450; Two Senior Bacteriological Technical Assistants, salary £336; and Three Bacteriological Technical Assistants, salary £216 per annum.

BEDFORD COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £174 10*s.* per annum. Also House Physician. Salary £152 10*s.* per annum, with board, &c.

BIRKENHEAD. BOROUGH HOSPITAL.—Junior House Surgeon. Salary £170 per annum, with board, &c.

BIRMINGHAM, CITY OF.—Female Doctor for Infant Welfare Work. Salary £350 per annum.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon. Salary £200 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

GREENWICH UNION INFIRMARY AND WORKHOUSE.—Assistant Medical Officer, unmarried. Salary £200 per annum, with rations, &c.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Two House Surgeons. Salary at rate of £100 per annum, with board, &c.

HULL ROYAL INFIRMARY.—Honorary Surgeon. Also Senior House Surgeon, unmarried. Salary £250 per annum, with board, &c.

MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS.—Locum Tenens Second Assistant Medical Officer, unmarried. Salary £400 per annum with board, &c.

MANCHESTER CORPORATION.—Temporary Assistant Tuberculosis Officer. Salary £450 pe annum.

PRINCE OF WALES'S HOSPITAL, Tottenham.—Medical Officer to Venereal Department. Also Assistant Medical Officer. Salary at rate of £300 and £100 per annum respectively.

ROCHESTER, KENT, ST. BARTHOLOMEW'S HOSPITAL.—Senior Resident House Surgeon. Salary at rate of £300 per annum, with board, &c.

ST. PANCRAS INFIRMARY (SOUTH). Pancras-road.—Female Assistant Medical Superintendent and Assistant Medical Officer for house adjoining. Salary at rate of £300 per annum.

SALOP COUNTY COUNCIL.—Temporary Assistant School Medical Officer. Salary at rate of £400 per annum.

SCOTTISH WOMEN'S HOSPITALS (N.U.W.S.S.).—Female Chief Medical Officer. Salary £400 per annum, with board, &c. Also Female Assistant Medical Officer. Salary at rate of £300 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Senior Student as Assistant to House Surgeons. Salary as arranged, with board.

WOOLWICH, METROPOLITAN BOROUGH.—Female Assistant Medical Officer of Health. Salary £350 per annum.

THE Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Sheriffdom of Lanark. Applications should be addressed to the Private Secretary, Scottish Office, Whitehall, S.W. 1, not later than Jan. 11th.

Births, Marriages, and Deaths.

BIRTHS.

PORTEOUS.—On Dec. 15th, at Newbury House, Weston-super-Mare, the wife of Captain H. B. Porteous, R.A.M.C. (T.F.), of a son.

MARRIAGES

STOWERS—GUNN.—On Dec. 19th, at St. Marylebone Parish Church, Captain Raymond Stowers, R.A.M.C., to Enid Elizabeth, younger daughter of the late R. Marcus Gunn, F.R.C.S., and Mrs. R. Marcus Gunn.

DEATHS.

MOLE.—On Dec. 21st, at College-road, Clifton, Bristol, Harold Frederic Mole, F.R.C.S. Eng., aged 51 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A CURIOUS ACTION OF MERCURY ON ALUMINIUM.

To the Editor of THE LANCET.

SIR,—In THE LANCET (Nov. 24th: Dr. Cameron Kidd; and again in Dec. 15th, p. 917, Captain M. H. Fleming) attention is drawn to a curious action of Hg upon Al. The phenomenon is as follows: If a trace of Hg, or of solid $HgCl_2$, is rubbed into a sheet of Al foil, that metal almost immediately becomes dulled, presently a white layer forms, and in a few moments a very striking arborescent growth of white fluffy material sprouts up. Close inspection, better with a pocket lens, reveals a *visibly jerky* and rapid upgrowth of the white columns, which may reach a height of half an inch or more. The tufts are very fragile and easily blown away. Captain Fleming states that he has demonstrated this phenomenon to many people, including chemists, and that none of them "understood the reason why."

For some years past I have been familiar with the phenomenon, and have often shown it to friends, and at my lectures on materia medica. The explanation is, I think, simple, and in fact, was correctly given in a note to Dr. Kidd's communication. But as Captain Fleming is apparently not yet convinced I may be allowed to supplement the note. Absolutely pure Al is not readily oxidisable in air. Commercial Al is not perfectly pure, and contains traces of Fe and Si. The impure metal is more easily oxidised than the pure. Although the surface of the commercial Al is lustrous, it is really covered with a thin film of oxide which hinders further change and interferes with the process of soldering. Junctions are effected by riveting or welding. When Hg is rubbed on Al foil it makes an amalgam of Hg and pure Al. This amalgam rapidly oxidises, even in dry air, and forms Al_2O_3. The fluffy growth is hastened and intensified by breathing upon it, and doubtless some $Al(OH)_3$ is formed. If the white fluff be dissolved in dilute HCl and excess of NH_4OH added, an abundant flocculent precipitate of $Al(OH)_3$ is obtained.

These facts are long, if not generally, known, and were observed by Matignon in 1900 and by Kohn-Abrest in 1904 (see references in "A Text-book of Inorganic Chemistry," edited by J. N. Friend, 1917, Vol. IV., p. 56): "Aluminium rapidly oxidises if the surface is amalgamated with Hg, an arborescent growth of Al_2O_3 quickly forming all over the metal."—I am, Sir, yours faithfully,

WALTER G. SMITH, M.D. Dub.,
King's Professor of Materia Medica and Pharmacy.

Dublin, Dec. 19th, 1917. Trinity College, Dublin.

To the Editor of THE LANCET.

SIR,—Your correspondents Dr. Cameron Kidd and Captain M. H. Fleming will probably be interested in the following extract from "The Evolution of Matter," by Dr. Gustave Le Bon, which I happened to come across to-day. It occurs in a chapter on "The Variability of Chemical Species," where experiments on three metals, aluminium, magnesium, and mercury, are thus alluded to: "It will then be seen that by putting the first two of these metals in the presence of traces of various substances—for example, distilled water which has served to wash out an empty flask previously containing mercury—it becomes possible so to modify their characteristics that, if classified according to their new properties, their places in the list of elements would have to be altered. Thereafter these metals, which are generally without any action on water, decompose it violently; the aluminium instantaneously becomes oxidised in air, becoming covered with thick tufts which grow under one's eyes, and which give to a plate of polished aluminium the look of a jungle." A footnote to the above says, "In Europe this experiment seems to have passed almost unnoticed. Dr. Parodi, of Cairo, says, however, that he has repeated it with perfect success, and apparently much to his own astonishment." The experiment is described and illustrated on p. 409.

I am, Sir, yours faithfully,

Watton, Norfolk, Dec. 21st, 1917. H. MALLINS, M.B.

THE BRITISH SCIENCE GUILD.

WE have received a copy of the sixth number of the *Journal of the British Science Guild* which contains reports of the proceedings of the Guild and some important correspondence on new educational schemes, and the great question of scientific training in regard to industrial progress. Sir William Mather has resigned the presidency and is succeeded by Lord Sydenham. The executive and sub-committees show a strong caste of leaders of scientific thought. Copies of the journal may be obtained at the offices of the Guild, 199, Piccadilly, London, W. 1, price 6*d.* each.

MILK CARDS AND PROFESSIONAL SECRECY.

AN interesting ethical point has arisen in Paris in regard to the issue of milk cards on the prefectural order of Oct. 30th last. Cards are issued entitling the delivery of milk for children, but in the case of adults a medical certificate is required indicating the nature of the ailment which makes the taking of milk a necessity, the daily quantity of milk desirable, and how long the supply is required. A number of Parisian doctors have felt that the signing of a certificate for such a purpose involves the betrayal of the customary professional secrecy between the medical man and his patient. The editor of the *Paris Médical*, in commenting on this position, suggests that this is not the case, inasmuch as it is the patient who asks for the certificate, and no information passes behind his back between his medical adviser and any lay authority. When the condition is one, such as syphilis or cancer, in which the divulging of the ultimate diagnosis might conceivably prejudice the patient the medical man is not bound to convey the whole truth, but only the truth in so far as it entitles his patient to special consideration. In the case of syphilis with digestive disturbance the entry "digestive trouble" would meet the case without any fear on the medical man's part that he was violating the oath of Hippocrates.

MALARIA PROBLEMS.

REFERRING to the question of primary and secondary malaria discussed in our annotation last week (p. 905), a correspondent recalls the two well-known cases of experimental infection in England at the London School of Tropical Medicine by anophelines brought from Italy (THE LANCET, 1900, ii., pp. 923, 954). In both these cases, which are of capital importance, the primary infection was associated with the presence of simple tertian parasites in the blood.

DISABLED OFFICERS INTERNED IN HOLLAND.

THE first party of some 300 commissioned and non-commissioned officers to benefit by the new exchange scheme are expected to reach Holland this week. The conditions are the same as those for internment in Switzerland, and include forms of disablement precluding from military service while not entitling their bearers to repatriation. The Hague and Scheveningen are the places at present set apart for internment. The British Red Cross in Holland (address, Heerengracht 13, The Hague) is taking an active part in preparation for the reception of the men.

COLONIAL HEALTH REPORTS.

A REPORT on the Straits Settlements for the year 1916, signed by Mr. F. S. James, Colonial Secretary, has been presented to Parliament. In the section devoted to vital statistics it is stated that the number of births registered during the year was 22,342 and of deaths 24,371. The estimated population was 797,739. The birth-rate has decreased from 29·25 to 28·15 per mille. The death-rate has slightly increased, being 30·70 per mille as against 29·15 in 1915. The principal causes of death were malaria (3346 cases), infantile convulsions (3735), tuberculosis (1870), beri-beri (1075), and dysentery (791). Dangerous infectious diseases notified in the colony during the year caused 122 deaths from small-pox, 17 from cholera, and 23 from plague.

Snow.—(A) No. (B) No. (C) The lighter bony structure, but it is practically negligible.

Medical Diary for the ensuing Week.

SOCIETIES.

HUNTERIAN SOCIETY, at the Royal Society of Medicine, 1, Wimpole-street, W.
WEDNESDAY.—5 P.M., Hunterian Lecture:—Sir Robert Jones, C.B.: War-time Orthopædic Surgery.

CHILD-STUDY ASSOCIATION (CONFERENCE OF EDUCATIONAL ASSOCIATIONS), Mathematical Theatre of University College, Gower-street, W.C.
THURSDAY.—5.30 P.M., Discussion on the Education of the Clever Child (opened by Mr. G. F. Daniells and Miss M. Berryman).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

TO SUBSCRIBERS IN THE UNITED STATES.

Messrs. Wm. Wood and Co., of New York, are relinquishing their Agency for the supply of THE LANCET in the United States at the end of the present year. The Manager of THE LANCET will be pleased to supply copies direct from the London Office to subscribers in the United States at the strictly prepaid rate of $8 for twelve months. Subscriptions may commence at any time. Drafts and Money Orders should be made payable to the Manager, Mr. CHARLES GOOD, 1, Bedford-street, Strand, London, W.C. 2, England.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on advertisement page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES.

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

The following journals, magazines, &c., have been received:—Annali di Medicina Navale e Coloniale, Archives de Médecine et Pharmacie Navales, Bulletin de l'Académie de Médecine, Journal of the British Science Guild, Philippine Journal of Science, Tropical Diseases Bulletin, Magazine of the London School of Medicine for Women, British Journal of Dental Science.

Iodogénol

IODINE in its MOST RELIABLE FORM. | PÉPIN | IODINE in its MOST RELIABLE FORM.

Iodogenol is a preparation containing Iodine in an organic, assimilable form, possessing about 38 times the physiological activity of that of Iodide of Potassium. This preparation has, according to the clinical reports of eminent Medical Men, succeeded where the usual Iodide treatment has failed.

Iodogénol does not produce Iodism or other bad symptoms.

***INDICATIONS.*—SYPHILIS, RHEUMATISM, the various phases of TUBERCULOSIS, GENERAL DEBILITY, &c.**

LITERATURE and CLINICAL REPORTS on REQUEST.

In prescribing please always specify HOMMEL'S Hæmatogen.

Samples Free and Carriage Paid on application to—

HOMMEL'S HÆMATOGEN, 36/36a, St. Andrew's Hill, Doctors' Commons, LONDON, E.C.

Antikamnia Tablets

Strongly Recommended in:

INFLUENZA & LA GRIPPE

For the headache, pain, and general soreness give a five-grain Antikamnia Tablet crushed with a little water; if the pain is very severe two tablets should be given. Repeat every 2 or 3 hours as required. One single ten-grain dose is often followed by complete relief.

NEURALGIA

In the Treatment of Neuralgia and Myalgic Pains Antikamnia Tablets are not only palliative, but, along with other measures, assist in ultimate cures; they also have a field of use in Rheumatic and Gouty Affections. In Neurasthenia, Hysteria, and Migraine they are a valuable adjuvant to the other recognised therapeutic measures.

LARYNGEAL COUGH

Frequently remains after an attack of La Grippe, and has been found stubborn to yield to treatment. There is an irritation of the larynx, huskiness, and a dry and wheezing cough, usually worse at night. The prolonged and intense paroxysms of coughing are controlled by ANTIKAMNIA & CODEINE TABLETS, and with the cessation of the coughing the laryngeal irritation subsides.
Antikamnia Tablets are the least depressing of all the drugs that can exercise so extensive a control of pain, and also least disturbing to the digestive and other organic functions.

Analgesic. Antipyretic. Anodyne.

Antikamnia Preparations in 1-oz. packages only.

JOHN MORGAN RICHARDS & SONS Ltd.,

46-47, Holborn Viaduct, LONDON.

THE DIETETIC VALUE OF COCOA

Of the beverages in common use (Tea, Coffee and Cocoa), Cocoa is the best, because

1. It is not a mere stimulant: it is also a true food.
2. Its stimulant value is similar to that of Beef Tea, and its nutritive value bears comparison with that of milk.

It is quickly absorbed in the stomach, leaving no undigested irritant residue, and is therefore pre-eminently suitable for invalids—

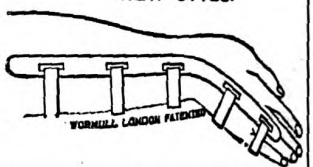
THE SYSTEM OF ALUMINIUM SPLINTING

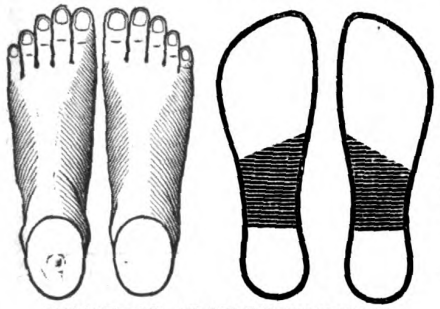


Devised by Sir FREDK. TREVES, Bart., G.C.V.O., C.B., &c.

OLD STYLE.

Twice the cost and twice the weight.
NOT ASEPTIC.

NEW STYLE.



Half the cost and half the weight. ASEPTIC.

By this system of Splinting with length 10 ft. of Side Bar weighing 1 lb., and 10 ft. Strip weighing 5 oz., a Splint for almost any part of the body can be made, or a number of smaller splints may be produced with the same quantity of material. This material can be sterilised and used over and over again without impairing its strength.

Nights . . . in the Sick Room

ANXIOUS hours are the night hours in the sick room. Hours of patient watching and of vigilance.

At such a time nothing can be so companionable as a restful, steady light. But it should be a light that needs no tending: a soft light that has no glare.

Such a light—large or small, according to the variety chosen—may be secured by the use of

Price's Night Lights

ROYAL CASTLE or CHILDS' *For Small Light*

PALMITINE STAR *For Medium Light*

93 Awards.

CLARKE'S PYRAMIDS
For Large Light and Heat.

From a health point of view, Price's Night Lights have everything to commend them. They do not vitiate the atmosphere. They are clean to handle and to use, whilst their light has just that unobtrusiveness so essential in the illumination of sick room and nursery.

Sold Everywhere.

PRICE'S PATENT CANDLE COMPANY Limited,
BATTERSEA, LONDON, S.W.11.

KEROL

KEROL combines all the properties which go to the making of an ideal preparation.

It has been shown to be practically non-toxic, non-irritant and non-corrosive—a combination of properties which make it the one preparation which can be used with perfect confidence wherever the use of either a disinfectant or antiseptic is indicated. It is of high and definite germicidal value and is perfectly homogeneous

KEROL is highly recommended by Bacteriologists and by prominent members of the Medical Profession.

KEROL CAPSULES

INTESTINAL. *These are of great value where intestinal antisepsis is indicated. In a comparatively short space of time the coli content of the intestine is reduced by over 99 per cent. They are non-irritant and perfectly safe*

STOMACHIC. *For use in cases of stomach fermentation and other gastric troubles, and are of great value in reducing the number of malign organisms prior to administration of treatment with lactic ferments, i.e., sour milk, etc.*

BLENOSAN
CAPSULES

As a routine
treatment for

GENITO-URINARY CONDITIONS.

BLENOSAN is a mixture of the finest East India Santal Oil with a specially prepared fluid extract of Kava-Kava. It is presented in the form of accurately-measured Capsules, and affords an ideal medicament for the treatment of all inflammatory conditions of the urethra.

BLENOSAN is an improvement upon the ordinary Santal, and the full proportion of the alpha resin of Kava-Kava ensures all the anæsthetic and diuretic properties of the root in a standardised and dependable form.

BLENOSAN CAPSULES consequently are indicated in all pathological conditions which affect the genito-urinary system, including acute Cystitis, Vaginitis, and Leucorrhœa, and where intense hyperæmia and swelling of the mucous membrane give rise to a diminution of the urinary canal.

BLENOSAN CAPSULES are well adapted for the continuous and systematic treatment of such cases, and are being used with excellent results by many of the most experienced and successful Physicians.

BLENOSAN CAPSULES can be prescribed for a course of treatment extending over two or three weeks.

MADE IN AUSTRALIA

"EUMENTHOL" TOOTH POWDER

(HUDSON)

A fragrant, palatable, non-toxic, non-irritant germicidal powder, being a combination of Formalin, Menthol, &c., with a diatomaceous earth in conjunction with a pure high-grade peroxide (MgO_2). The Menthol is in chemical combination with Formalin to form the new antiseptic compound, Dimenthol-Formal, CH_2 ($C_{10}H_{19}O_2$) M.P. 56, 5°C. (Brochet), and unites an antiseptic action twice more powerful than Sublimate, with a very decided effect in hardening the Gums. A strength of 1 in 1000 kills all the salivary bacilli in less than two hours. Dessirier recommends Dimenthol-Formal for the treatment of aphthæ.

"Eumenthol" Tooth Powder on dissociation (in contact with water or the Oral Fluids) liberates free active Oxygen, and Hydroxide of Magnesia in a minutely divided state is produced.

THE LANCET states: "This Tooth Powder is designed on sound principles and is very agreeable to use. The distinctive feature about it is that, in addition to some approved germicides, it contains MgO_2, which readily parts with free oxygen, as our experiments have shown."

Vitafer

The All-British Tonic Food

The NORWICH

CRÊPE ✚ BANDAGE

SUPERIOR ENGLISH MANUFACTURE

Extremely elastic, but contains no rubber.

FAST WOVEN EDGES.

Invaluable for all binding purposes. Entirely displaces bandages of rubber and elastic web. Considerably more durable, although less than one-third the cost of rubber or elastic web. Varicose veins and other ailments requiring the use of bandages usually demand *warmth* as well as support. The Norwich Crêpe Bandages, containing wool, provide this warmth and do not absorb grease. May be thoroughly cleansed by the use of *hot* (not boiling) soapy water, with the addition of a little ammonia or soda. Healthy and comfortable to wear, giving the necessary firmness, yet yielding to every movement. Self-clinging and self-adjusting.

THE BANDAGE THAT CAN BE STERILIZED.

IMPORTANT.—The edges will not fray out nor ravel.

"It's the greatest comfort in the world for every case of Varicose Veins."

Made and supplied to the leading wholesale houses, neatly wrapped in labelled packages. Inexpensive and high in quality; universally commended by the medical and nursing professions. Send for prices and samples to the Sole Manufacturers:

THE NORWICH CRAPE CO. (1856), LTD.,

St. Augustine's Silk Mills, Norwich, Eng.
